STANDARD ECMA-12

FOR

DATA INTERCHANGE

ON 9 TRACK MAGNETIC TAPE

AT 31.5 ROWS PER mm (800 rpi)

2nd Edition — June 1970
BRIEF HISTORY

On April 30, 1965, ECMA adopted their Standard ECMA-6 for a 7 Bit Character Code for Input and Output purposes. In the form adopted, it included no proposals for implementation in media which were deliberately left as the subject for future standards. The Standard ECMA-5 defined Data Interchange on 7 Track Magnetic Tape at a density of 8 bit per mm.

This new Standard ECMA-12 is directed to a Data Interchange on 9 Track Magnetic Tape at a density of 31.5 bit per mm. It has been adopted by the General Assembly of ECMA on Nov. 28, 1967.

THIS 2nd EDITION SUPERSEDES THE VERSION DATED NOVEMBER 1967.

SECTION III

RELATION OF RECORDED BITS ON TAPE TO CODED CHARACTERS

3.1 Recording Conventions
3.2 Significance of Binary Digits
3.3 Filling of Unused Positions on Tape
3.4 Representation of ECMA-7 Bit Coded Characters
3.5 Control Blocks

APPENDIX A

APPENDIX B
Standard ECMA-5 sets out the parameters for magnetic tape which may be used to interchange data between electronic data processing installations, at the low density of 8 rows per mm.

This Standard ECMA-12 sets out the same parameters but at the higher density of 31.5 rows per mm.

The parameters which are required to define adequately a magnetic tape for data interchange fall within three sections:

The first deals with the characteristics of the magnetic tape itself and of the reel on which it is wound.

The second deals with the dimensional and magnetic characteristics of the recording of data on the tape and the method of checking.

The third deals with the relation of the bits on a tape to coded characters and the format on data files.

Section I deals with the minimum number of physical parameters of the tape with test methods where necessary. The intention is to ensure that the properties of tape used for data interchange shall not vary sufficiently to nullify the effect of the requirements of the Standard.

Section II is based on the NRZI method of recording. A particularly important part of this section is the definition of the method of checking the information; data are arranged in blocks, with transverse and longitudinal parity-checks, together with a Cyclic Redundancy Check Character.

Section III establishes a series of conventions to ensure that there is no ambiguity in the meaning given to the recorded bits on tape. Standard ECMA-13 defines magnetic tape labels.

In ECMA-5, the problems encountered due to the packing density of 8 rows per mm did not create any serious difficulty with respect to the definitions or the quantitative values assigned to the various parameters.

This present Standard, however, represents certain definitions and quantitative values in clauses 2.4 and 2.5 which provide the most meaningful checks possible at the present time. It is emphasized that this Standard is concerned with the specification of magnetic tape and as such it is not appropriate that it should make recommendations in reaction to writing or reading equipment. Nevertheless, when writing an interchange
tape in accordance with this Standard, and especially when reading it, certain difficulties and technical shortcomings have to be faced, some of which are set out below:

1) The positioning of the data on the tape, which is very dependent on the particular guidance geometry of the tape transports.

2) The coating thickness of the tape, which has an appreciable effect on the position of bits due to the pulse crowding factor on the tape as specified.

3) The characteristics of the head and in particular the crosstalk factor.

4) The initial transient conditions as the tape is started from rest.

5) The problem of defining and utilizing the reference edge.

6) Speed variations at the time of writing and reading which could also include different nominal speeds.

7) Timing constraints due to coding and pattern sensitivity.

Thus it has been recognized that it is not reasonable to expect a sender of magnetic tape in an exchange to be equipped to monitor the precise position of flux reversals on the tape, either longitudinally or square to the reference edge. This Standard, therefore, provides a guide to the settings of a "control device" which reads the peak flux points on the tape pass during which writing occurs.

The control device values may vary from the design centre values stated in clause 2.5.2.1 (i) and 2.5.2.1 (ii) under the circumstances summarized above. When they vary, they must vary in such a manner, that the requirement of clause 2.5.2.1 (iii) is met.

Design centre values actually used have to be chosen in such a way that the number of read errors resulting from actual variations around these centre values (i.e. the control device values) are kept within an acceptable limit. This also assumes that read errors due to unfavourable combinations of tolerances cannot reasonably be expected to occur again on a repeat (write or read) pass.

In Appendix A recommendations are made in connection with the transportation of the tape and in Appendix B notes are given concerning the use of the Cyclic Redundancy Check. These Appendices are not part of the Standard.
SCOPE

To provide a specification for 12.70 mm 9 track magnetic tape to enable mechanical and magnetic interchangeability of tape between information processing systems. This Standard refers solely to magnetic tape for digital recording on which the direction of magnetization is nominally longitudinal as opposed to nominally transverse.

DEFINITION

For the purpose of this Standard the following definitions apply:

Magnetic Tape
Tape which will accept and retain magnetic signals intended for input, output and storage purposes on computers and associated equipment.

Reference Tape
A tape which has been arbitrarily selected for a desirable property.

Secondary Reference Tape
A tape intended for routine calibrating purposes, the performance of such a tape to be known and stated in relation to that of a reference tape.

Static Skew
The average width of a band of tape, perpendicular to the reference edge, containing all the bits of a row.

Reference Alignment Tape
A reference tape recorded continuously in all 9 tracks with static skew of less than 1.27 micrometer.

Reference Field
The minimum field applied to the Reference Recording Field Tape which causes an output signal equal to 95% of the maximum signal output at the specified packing density.

Reference Recording Field Tape
The Reference tape which is selected as a standard for recording field.

Reference Signal Output Tape
The Reference Tape which is selected as a standard for signal output.
Reference Signal Level
The signal level which would be obtained from a Reference Signal Output Tape.

Reference Pulse Width Tape
The Reference Tape which is selected as a standard for pulse width.

Saturating Field
The minimum field which can be applied to a tape above which no significant increase of signal output will result.

Erasing Field
A unidirectional field of sufficient strength to remove the signals from the tape.

Track
A longitudinal area on the tape along which a series of magnetic signals may be recorded.

Reference Edge
The reference edge is that which is chosen arbitrarily as a reference for the layout of tracks and the siting of markers. (See Clause 2.1.)

In Contact
An operating condition in which the oxide side of a tape is in contact with magnetic head.

Leaders
Those integral parts of a complete tape which lie outside the tested portion.

Print Through
Any unwanted signals induced in one layer of tape by the field of a deliberately recorded signal in an adjacent layer or layers.

Pulse Packing Density
The number of reversals of magnetization per unit length of track.

Reel
A reel has no tape wound on it. A full reel is a reel completed with a tape.
SECTION I - CHARACTERISTICS OF TAPE AND SPOOL

TEST ENVIRONMENT: Unless otherwise stated, all measurements made on a tape to check the requirements of this specification and all tests prescribed for a tape in the document will be carried out under the environmental conditions of 23°C ± 2°C and 40% RH to 60% RH relative humidity, after at least 24 hours conditioning.

1.1 Width of Tape

For the purpose of this specification the width of the tape shall be 12,7 mm ± 0
- 0,1 mm.

1.2 Tape Length

Tape which is splice free and which has been tested shall be available in any length not exceeding 753 metres and the length is required to be stated, it shall be subject to a tolerance of + 3% - 0%.

1.3 Material

The tape shall consist of a base material (oriented polyethylene terephthalate film or its equivalent), coated on one side with a strong yet flexible layer of ferromagnetic material dispersed in a suitable binder.

1.4 Thickness of Tape

a) Base. The nominal thickness of the base material shall be 0,036 mm.

b) Overall. The overall thickness of tape and oxide coating, not including any markers, shall be 0,048 mm + 0,008 mm with a maximum oxide coating thickness of 0,015 mm.

Other tape thicknesses would satisfy the requirements of this proposal but are not standardized at this time.

1.5 Change in Width

The material shall be such that no change in the tape width greater than 0,25% can occur when the tape has been subjected to any combination of temperature and humidity within the ranges of 10°C to 50°C and 20% R.H. to 80% R.H.

1.6 Elastic Properties

The elastic properties of the tape shall be such that when subjected to a tension of 10 N for a period of three minutes under any combination of temperature and relative humidity within the ranges of 10°C to 50°C and 20% to 80% R.H., the permanent elongation measured with negligible tension after a second three minutes interval shall be less than 0,5%. The elastic modulus for a single smooth application of tension in three minutes or less, down to the time set by the inertia of the tape itself, shall be
such that the elongation is less than 0.5\% under a tension of 4.5 N. For the convenience of testing, the measurement may be performed with a tension applied for three minutes.

1.7 Longitudinal Curvature
There shall be a minimum radius of curvature for the edge of the tape, defined and tested by allowing a 1m length of tape to unroll and assume its natural curvature on a flat surface. The minimum radius shall be 33 m, which, if measured over an arc of circle, corresponds to a deviation of 3.8 mm from a 1 m chord.

The tape, when new, shall be tested in accordance with Clauses 1.8 to 1.17

1.8 Packing Density
For the purpose of testing tape in accordance with this specification the pulse packing density shall be not less than that of the system with which the tape is to be used and not more than 32 flux reversals per mm of track. In addition, for this test the flux reversals shall be uniformly spaced.

1.9 Recorded Current
The relationship between the recording current and the current required to produce the reference field shall be 200 to 220\% of the current required to produce the reference field.

1.10 Average Peak Output
The average peak output is defined as the average peak value of the output voltage over at least 1000 consecutive pulses. When a tape has been recorded with a recording current defined in Clause 1.9 on all tracks, then played back on a system, each channel of which has been calibrated by means of a Secondary Reference Signal Output Tape, the average peak output shall be within ± 10\% of the output of the Reference Signal Output Tape.

When performing this test, the output signal shall be measured on a corresponding track for the same relative pass for both Secondary Reference Output Tape and the tape under test i.e. Read-Whilst-Write or Read-on-first-pass-after-Write.

1.11 Ease of Erasure
When a tape has been recorded according to this specification and then passed through a unidirectional steady erasure field of 79500 A per m (1000 oersteds) the average peak output level of the remaining unwanted signal plus tape noise shall not exceed 3\% of the output of the Reference Signal Output Tape. The erasure field shall be reasonably uniform; e.g. the field in the middle of a selenoid.
1.12 Tests for Drop-Outs and Drop-Ins

These tests shall be carried out in the In-contact condition and over the entire tested area which shall extend from 0.2 m before the Beginning-of-tape-reflective-marker (BOT) to 3 m beyond the End-of-tape-reflective-marker (EOT).

1.13 Drop-Outs

When a tape has been recorded with all permissible consecutive reversals of recording current, as defined in Clause 1.9 on all tracks, then played back on a system each channel of which has been calibrated as in Clause 1.10 any signal from any track which is less in amplitude than 50% of the output of the Reference Signal Output Tape is a drop-out.

When performing this test, the output signal shall be measured on the same relative pass for both the Secondary Reference Output Tape and the tape under test i.e. Read-whilst-Write or Read-on-first-pass-after-Write.

1.14 Drop-Ins

When a tape has been recorded on all tracks by a constant recording current as defined in Clause 1.9 then played back on a system calibrated as defined in Clause 1.10, any signal from any track which exceeds in amplitude 10% of the output of the Reference Signal Output Tape is a drop-in.

When performing this test, the output signal shall be measured on the same relative pass for both the Secondary Reference Output Tape and the tape under test (i.e. Read-whilst-Write or Read-on-first-pass-after-Write).

1.15 Rejected Regions

A rejected region is an area of tape extending across the full width of the tape and not more than 10 mm in length which contains areas of tape which on two consecutive tests exhibit drop-outs or drop-ins.

NOTE: The method proposed in this Standard for data interchange allows the use in practical conditions of tapes with rejected regions (see Clause 2.15).

1.16 Testing Tape under Operating Conditions

Machines are available for testing the performance of tape under operating conditions. The type of machine used and the acceptable level of the numerical values obtained within the framework of this Standard shall be determined by arrangement between the user and the manufacturer or supplier.

1.17 Magnetic Properties

The magnetic properties of the tape shall be those defined by the testing procedures in Clauses 1.8 to 1.14
inclusive and not as defined by B-H loops or similar parameters.

1.18 Print-Through

A tape for testing shall be stored for 8 hours at 60°C during which time changes shall be made to the relative humidity within the range 20 to 80%. Immediately after the end of this period the peak print-through signal shall not exceed 1% of the reference signal.

1.19 Reflective Markers

Reflective markers used to indicate beginning and end of tape shall be placed on the side of the tape which does not carry the oxide coating. The Beginning-of-tape marker (BOT) shall be adjacent to the reference edge, and the End-of-tape-marker (EOT) shall be adjacent to the opposite edge. (See Clause 2.1 and Fig. 1).

The width of the markers shall be 4,8 mm ± 0,4 mm, length 30,0 mm ± 5 mm and their thickness when measured in situ shall not exceed 0,013 mm.

The beginning of tape marker shall be placed 4,3 m to 5,6 m from the beginning of the tape and the end of tape marker shall be placed 7,6 m + 1,5 m - 0 m from the end of the tape.

The surface of the reflective marker shall be non-conductive.

1.20 Reels

1.20.1 Reels shall be constructed such, that any profile section taken through the centre axis of the reel conforms to Fig. 2 except where taken so as to pass through the relieved portion of the write-enable ring groove. The section shall, in this case, conform to the profile of Fig. 2 with appropriate deviations permitted at the ring groove relief as illustrated in the detail.

1.20.2 Reels are not symmetrical, the flange differing primarily as to the presence or absence of the write-enable ring, which must be adjacent to the mounting pedestal for correct machine operation.

1.20.3 Hub and flanges need not to be integral, but may be separate parts as the manufacturer's option as long as all other requirements of this standard are met.

1.20.4 All dimensions shown in Figure 2, including those in detail section, shall be held to the tolerances specified in Table 1.

1.20.5 In the hub, the surface between A and D is the reference for reel mounting.
1.20.6 With respect to the mounting reference surface, any point of the inside surfaces of the flanges, defined by dimensions J and N, must fall within the specified tolerances.

1.20.7 The outside cylindrical surface of the hub shall be concentric with the bore (dimensions C and A respectively of Figure 2) within 0.25 mm.

1.20.8 Thickness of the flange may be varied, but must fall within the cross-hatched envelope defined by dimensions Kr, Jr, N, Kt. Bosses, ribs, or raised designs are permitted within the same envelope.

1.20.9 A finger guide on the front of the reel is necessary, but size, shape and location are optional (see Fig. 2).

1.20.10 Flange holes are optional. When provided, number, size and shape are optional.

1.20.11 The full reel should be balanced about its normal axis of rotation irrespective of the existence or lack of flange holes. Any amount by which the full reel is out of static balance shall not exceed 1.5 g cm.

1.20.12 The moment of inertia of the full reel shall not exceed 102.5 x 10³ g cm². The maximum moment of inertia of any reel shall not exceed 50 x 10³ g cm².

1.20.13 Dimension A shall not reduce below 93.47 mm when the reel is fully loaded with tape wound at 33 N constant tension.

1.20.14 Owner Identification. A labelling area shall be provided on the front flange of the reel to provide ownership identification.

1.20.15 Manufacturer's Reel Identification. The manufacturer's identification may be placed on the reel.

1.20.16 Interchange Label. A labelling area shall be provided on the front flange. Suitable labels shall be used for marking the contents of the reel of the tape. Adhesive labels, if employed, shall leave no residue when removed. The use of pencil or similar erasable marking is not allowed.

1.20.17 When installed in the write enable ring groove, the top surface of the write enable ring must be such that it does not protrude above the mounting reference surface.

1.20.18 All write enable rings must have a tab to facilitate removal from the groove.

1.20.19 Dimensions and materials used must be such that the write enable ring may be installed and removed with reasonable effort and remain seated during normal use. Furthermore, the ring must be constructed so as not to interfere with normal tape transport performance.

SECTION II - FORM OF RECORDING

2.1 Reference Edge
When a tape is lying flat with the oxide side uppermost and the direction of movement for recording from left to right, the reference edge is the one farthest from an observer or nearer the top of a page (see Fig. 1).

2.2 Track Configuration
There will be nine tracks on the tape. The written track width shall be 1,09 mm minimum and 1,12 mm maximum. The distance from the centre line of any track to the reference edge shall be 1,397 (n-1) + 0,74 mm ± 0,080 mm, where track n is the track number.

2.3 Track Identification
The tracks shall be numbered consecutively from 1 to 9, with track 1 adjacent to the reference edge (See Fig. 3).

2.4 Density of recording
The nominal density shall be 31,5 transverse rows per mm.
The maximum written row spacing variation allowed shall be ± 3% of the nominal spacing of 31,75 micrometer. The capability of a machine in this respect shall be measured over a 10 second period, at the extremes of operating conditions, reading a continuously and evenly recorded tape with 31,5 flux reversals per mm in all tracks.

2.5 Skew

Skew is defined as the deviation of the bits within the recorded row during reading from time coincidence (converted to apparent length) when measured in the control device.

2.5.1 Static Skew

The equipment used for recording tapes at 31,5 r.p.mm must be capable of recording 4,71 micrometer or less absolute static skew. This capability shall be measured on a tape which has been recorded continuously with 31,5 flux reversals per mm in all tracks. This maximum static deviation within a character is the value of static recorded skew. Both character polarities must meet this criterion.

2.5.2 Write Quality Check

During the writing of a 31,5 r.p.mm interchange tape, the write check operation will determine bit timing (converted to apparent length) and signal amplitude.

**NOTE:** On equipment that is not capable of reading during the write pass, bit timing and signal amplitude may be checked on the first read pass on the same equipment.

2.5.2.1 Bit Timing (converted to apparent length)

To determine bit timing, from leading edge to leading edge, the following conditions must be considered together:

(i) The timing between the first detected bit of successive rows shall be measured greater than a design centre value which shall exceed 22,9 micrometer.

(ii) The timing between the first detected bit and the last detected bit of a row shall be measured less than a design centre value which shall not exceed 10,8 micrometer.

(iii) There shall be a minimum apparent space between any bits of successive rows of 11,2 micrometer.

2.5.2.2 Reference Signal Amplitude

No ONE bit amplitude level shall be less than 35% of the average Reference Signal Level on the Write Quality Check.
2.6 Block Length
All blocks for data interchange shall consist of not less than 18 data rows and not more than 2048 data rows and in addition a cyclic redundancy check row and a longitudinal check row. Blocks of less than 18 rows may exist on a data interchange tape, but do not form part of the data to be interchanged.

2.7 Cyclic Redundancy Check
At the end of each block (except Tape Mark function blocks) a character shall be written on tape for the possible recovery of single track errors. This character shall be called the Cyclic Redundancy Check (CRC) character. In tape mark blocks ZERO bits are written in all tracks for the CRC character.

Consider the contents of a 9 position register to be \( C_1 \) to \( C_9 \) with the following track assignment:

<table>
<thead>
<tr>
<th>Track No.</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit Register</td>
<td>( C_6 )</td>
<td>( C_8 )</td>
<td>( C_2 )</td>
<td>( C_3 )</td>
<td>( C_4 )</td>
<td>( C_1 )</td>
<td>( C_5 )</td>
<td>( C_9 )</td>
<td>( C_7 )</td>
</tr>
</tbody>
</table>

The CRC character can be considered as being constructed as follows:

a) All data rows in the block are added to the CRC register without carry (bit position \( n \) exclusive OR ed to \( C_n \)).

b) Between additions the CRC register is shifted one position \( C_1 \) to \( C_2 \) etc. to \( C_9 \) to \( C_1 \).

c) If shifting causes \( C_1 \) to become 1, then the bits being shifted into positions \( C_4 \), \( C_5 \), \( C_6 \) and \( C_7 \) are inverted.

d) After the last data row has been added, the CRC register is shifted once more in accordance with b) and c).

e) To write the CRC character on tape, the contents of all positions except \( C_4 \) and \( C_6 \) are inverted. The parity of the CRC character will be odd for an even number of data rows in the block and even for an odd number of data rows in the block. The CRC character may be all zeroes. See Appendix B.

2.8 Parity of Data Rows
The parity track shall be track 4 and all data rows shall have overall odd parity.

2.9 Longitudinal Check Row
This row, written at the end of a block including the CRC characters, shall make the longitudinal parity of each track even for that block.

2.10 Check Row Gaps
There shall be gaps of 0.127 mm \( \pm \) 0.030 mm between the last row of recorded data and the cyclic redundancy check character; and between the cyclic redundancy check character and the longitudinal check row.
2.11 Inter-Block Gap
The gap shall be 15.25 mm nominal
12.70 mm minimum
7.6 mm maximum

2.12 Erase Length
The minimum erase length shall be 51 mm.
The maximum erase length shall be the length occupied
by 10 erase operations.
One erase operation is defined as erasing of a length
of tape not greater than the length of the original
block + 57 mm.

2.13 Load Point Gap
There shall be a minimum load point gap of 75 mm and a
maximum of 7.6 m from the lagging end of the Beginning-
of-tape-reflective-marker to first row on tape.
There shall be no magnetic signals on the tape between
the leading end of this marker and the first row.
The recording area on the tape shall not extend more
than 3 m beyond the leading edge of the End-of-tape-
marker.

2.14 Method of Recording
The Non Return to Zero Mark (NRZ1) method of recording
shall be used where a one is represented by a change
of direction of magnetization.
The recording field shall be between 120 and 220% of the
reference field.
The tape shall be magnetized such that the beginning of
tape is a magnetic North Pole and the end of tape is a
magnetic South Pole, at end of recorded section of tape.
This requirement shall apply also to erase sections and
interblock gaps.
The full width of the tape is DC erased in the specified
direction.

2.15 Quality of Tape for Data Interchange
Information written must be valid at the level of 35%
of that from the Reference Output Tape under the same
conditions. Tape shall not be employed for data inter-
change where the number of gaps which have been elong-
ated due to erase instructions exceeds two or 0.5% of
the total number of blocks written, whichever is larger.
No permanent parity errors are permissible in the data
to be interchanged.

2.16 Data Content
All 256 binary combinations are permissible in the 8
data tracks of each row.
2.17 Transportation

Responsibility for ensuring that adequate precautions against damage taken during shipment shall lie with the sender.

Since it is essential for a data bearing tape to be received in the same condition as it was sent out, guidance is given in Appendix A.
SECTION III

RELATION OF RECORDED BITS ON TAPE TO CODED CHARACTERS

3.1 Recording Conventions
The following conventions shall be adopted to relate binary digits recorded on the tape to coded characters or to digits within computers or similar equipment. (These also cover the case of data arranged as sequences of arbitrary binary digits).

Any arrangement of data, which is to be interchanged, shall comply with the conventions of clauses 3.2, 3.3, and 3.4.

3.2 Significance of Binary Digits
Within any one row on tape the direction of increasing significance of the binary digits shall be from \( b_1 \) to \( b_n \) and in accordance with the track identification in Clause 3.4.

3.3 Filling of Unused Positions on Tape
In certain cases the arrangement of binary digits in groups of 8, within each row on tape, may not fit in exactly with the sizes of groups of digits in the equipment with which the data-interchange tape is used. In these cases it may be necessary to use "fill in" digits on the tape. Then:

i) The "fill in" digits shall be ZEROS

ii) The "fill in" digits shall be placed at the more significant bit position of a row.

3.4 Representation of ECMA 7 Bit Coded Characters

3.4.1 Sequence of coded Characters
Considering the recorded data as being in character form, the sequence of characters from the start towards the finish of a block shall correspond to the normal left to right sequence of a written line.

3.4.2 Arrangement of ECMA 7 Bit Coded Characters
The 7 bit relationship to the 8 positions of the environment is:

\[
\begin{array}{cccccccc}
\# \text{ of the } 7 \text{ bits of the code} & 0 & 7 & 6 & 5 & 4 & 3 & 2 & 1 \\
\# \text{ of the } 8 \text{ positions of the environment} & 8 & 7 & 6 & 5 & 4 & 3 & 2 & 1 \\
\end{array}
\]

where \( 0 \) is a high-order bit with value 0.
The relationship of the 9 tracks of the 8 positions of the environment and of the parity position is:

Parity (P) and

<table>
<thead>
<tr>
<th># of the 8 positions of the environment</th>
<th>P</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td># of the 9 tracks</td>
<td>4</td>
<td>7</td>
<td>6</td>
<td>5</td>
<td>3</td>
<td>9</td>
<td>1</td>
<td>8</td>
<td>2</td>
</tr>
</tbody>
</table>

3.5 Control Block

For the purpose of separating data, single row control block (known as a Tape Mark) shall be allowed. This block shall be accompanied by a longitudinal check row. The Tape Mark shall be represented by "ONE" bits in tracks 2, 3 and 8 only.

**NOTE:** The tape mark specified above is that internationally recognized, but other marks are also in common usage. The combination 000 1111 is widely used and users of this specification are advised to ensure that interchanged tapes carry mutually recognized marks.
APPENDIX A

Transportation of data bearing magnetic tape involves three basic potential hazards:

1. IMPACT LOADS AND VIBRATIONS: which could cause damage to the reel, or movement within the tape pack, with consequent loss of wind tension.

RECOMMENDATION
1.1 The free end of the tape should be secured to prevent any tendency to unwind.
1.2 The use of a rigid plastic container free from dust or other extraneous matter.
1.3 The plastic container(s) to be fitted into a rigid box containing adequate shock absorbent material.
1.4 The final box must have a clean interior and a lid construction that provides sufficient sealing to prevent the ingress of dirt and water.
1.5 The orientation of the reels within the final box should be such that their axes are horizontal.
1.6 The final box should be clearly marked to indicate its correct orientation.

2. EXTREMES OF TEMPERATURE AND HUMIDITY: which could set up stresses within the body of the tape.

RECOMMENDATION
2.1 Extreme changes in temperature and humidity should be avoided wherever possible.
2.2 After completion of the writing operation, the tape should be wound fully on to the take-up reel and then completely rewound on to the spool to be interchanged, at a tension of 1.4 to 2.8 N.
2.3 Whenever a tape is received it should be conditioned in the computer environment for a period of 2 - 6 hours, depending upon the type of transportation used.

3. EFFECTS OF STRAY MAGNETIC FIELDS: which would possibly cause corruption of data.

RECOMMENDATION
A nominal spacing of not less than 8 cm should exist between the magnetic tape reel and the outer surface of the final container in which case it is considered that the risk of corruption will be negligible.
APPENDIX B

Use of CRC

When reading, the CRC register is controlled as it was for writing until the last data character has been added and the final shift made. The CRC character on tape is then added to it.

To test for an error, the register is read out inverting all positions except 4 and 6. If the masked output of any position is a ONE an error has been detected.

To determine whether the errors occurred in a single bit position and, if so, which, an Error Pattern must be generated. This pattern must then be compared with the error indicating pattern in the CRC register.

Consider the contents of a 9 position error pattern register to be E₁ to E₉ corresponding to C₁ to C₉ of the CRC register. The error pattern can be considered as being constructed as follows:

(a) Whenever a character parity error is detected for a data row or CRC character, a one is added without carry to E₉ (1 exclusive or E₉).

(b) Between the reading of each character the error pattern register is shifted one position E₁ to E₂ etc. to E₉ to E₁.

(c) If, at the time of shifting, E₉ = 1 shifts to E₁ = 1, E₃, E₄, E₅ are inverted to E₄, E₅, E₆ and E₇.

To determine the track in error, a series of comparisons is made between the contents of the error pattern register and the CRC register. The CRC register, read out through the mask which inverts all positions except C₄ and C₆, is compared with the error pattern register.

The first comparison is direct: E₁ to C₁. If all positions match, the error was in the track associated with C₉ (b₁).

The CRC register is then shifted once, according to the rules b) and c) above, between each comparison. This is continued until a match is obtained or until a maximum of nine comparisons (eight shifts) have been made. The bit position in error corresponds to C₀ through C₁ for a match on the first through nine comparisons respectively.

There are two conditions for the final contents of the CRC register for which an uncorrectable error has been detected and for which an incorrect track in error indication will be obtained if comparisons are made. These are:

(a) C₁ through C₉ all ZERO

(b) C₄ and C₆ zero, all other positions containing ONE (the read-out mask).

Comparison must not be made when either of these two conditions exist. If a track in error indication is obtained, the error block may be re-read. The output of the track in error is then inverted whenever the parity of a character is incorrect.
NOTES:
1. Reflector shall be firmly attached to tape with its own adhesive back and shall be free of wrinkles.
2. Reflector shall not protrude beyond edge of tape.

Fig. 1
NOTES:
The tape is shown with oxide side up, Read/Write head on same side as oxide. Tape shown representing 1 bits in all tracks, NRZ 1 recording, 1 bit produced by reversals of flux polarity, tape fully saturated in each direction.
