1. Introduction
The Universal Disk Format (UDF) specification defines a subset of the standard ECMA 167 3rd edition. The primary goal of the UDF is to maximize data interchange and minimize the cost and complexity of implementing ECMA 167.

To accomplish this task this document defines a Domain. A domain defines rules and restrictions on the use of ECMA 167. The domain defined in this specification is known as the “OSTA UDF Compliant” domain.

This document attempts to answer the following questions for the structures of ECMA 167 on a per operating system basis:

> Given some ECMA 167 structure X, for each field in structure X answer the following questions for a given operating system:

1) When reading this field: If the operating system supports the data in this field then what should it map to in the operating system?

2) When reading this field: If the operating system supports the data in this field with certain limitations then how should the field be interpreted under this operating system?

3) When reading this field: If the operating system does NOT support the data in this field then how should the field be interpreted under this operating system?

4) When writing this field: If the operating system supports the data for this field then what should it map from in the operating system?

5) When writing this field: If the operating system does NOT support the data for this field then to what value should the field be set?

For some structures of ECMA 167 the answers to the above questions were self-explanatory and therefore those structures are not included in this document.

In some cases additional information is provided for each structure to help clarify the standard.

This document should help make the task of implementing the ECMA 167 standard easier.
1.1 Document Layout

This document presents information on the treatment of structures defined under standard ECMA 167.

This document is separated into the following 4 basic sections:

- **Basic Restrictions and Requirements** - defines the restrictions and requirements that are operating system independent.
- **System Dependent Requirements** - defines the restrictions and requirements that are operating system dependent.
- **User Interface Requirements** - defines the restrictions and requirements which are related to the user interface.
- **Informative Annex** - Additional useful information.

This document presents information on the treatment of structures defined under standard ECMA 167. The following areas are covered:

- Interpretation of a structure/field upon reading from media.
- Contents of a structure/field upon writing to media. Unless specified otherwise writing refers only to creating a new structure on the media. When it applies to updating an existing structure on the media it will be specifically noted as such.

The fields of each structure are listed first, followed by a description of each field with respect to the categories listed above. In certain cases, one or more fields of a structure are not described if the semantics associated with the field are obvious.

A word on terminology: in common with ECMA 167, this document will use **shall** to indicate a mandatory action or requirement, **may** to indicate an optional action or requirement, and **should** to indicate a preferred, but still optional action or requirement.

Also, special comments associated with fields and/or structures are prefaced by the notification: "**NOTE:**"
1.2 Compliance

This document requires conformance to parts 1, 2, 3 and 4 of ECMA 167. Compliance to part 5 of ECMA 167 is not supported by this document. Part 5 may be supported in a later revision of this document.

For an implementation to claim compliance to this document the implementation shall meet all the requirements (indicated by the word shall) specified in this document.

The following are a few points of clarification in regards to compliance:

- **Multi-Volume support is optional.** An implementation can claim compliance and only support single volumes.
- **Multi-Partition support is optional.** An implementation can claim compliance without supporting the special multi-partition case on a single volume defined in this specification.
- **Media support.** An implementation can claim compliance and support a single media type or any combination. All implementations should be able to read any media that is physically accessible.
- **Multisession support.** Any implementation that supports reading of CD-R media shall support reading of CD-R Multisessions as defined in 6.10.3.
- **File Name Translation** - Any time an implementation has the need to transform a filename to meet operating system restrictions it shall use the algorithms specified in this document.
- **Extended Attributes** - All compliant implementations shall preserve existing extended attributes encountered on the media. Implementations shall create and maintain the extended attributes for the operating systems they support. For example, an implementation that supports Macintosh shall preserve any OS/2 extended attributes encountered on the media. An implementation that supports Macintosh shall also create and maintain all Macintosh extended attributes specified in this document.
- **Backwards Read Compatibility** – An implementation compliant to this version of the UDF specification shall be able to read all media written under previous versions of the UDF specification.
- **Backwards Write Compatibility** – UDF 2.0x structures shall not be written to media that contain UDF 1.50 or UDF 1.02 structures. UDF 1.50 and UDF 1.02 structures shall not be written to media that contain UDF 2.0x structures. These two requirements prevent media from containing different versions of the UDF structures.
1.3 General References

1.3.1 References

IEC 908:1987 Compact disc digital audio system

ISO/IEC 10149:1993 Information technology - Data Interchange on read-only 120mm optical data discs (CD-ROM based on the Philips/Sony "Yellow Book")

Orange Book part-II Recordable Compact Disc System Part-II, N.V. Philips and Sony Corporation

Orange Book part-III Recordable Compact Disc System Part-III, N.V. Philips and Sony Corporation

ECMA 167 ECMA 167 3rd edition is an update to ECMA 167 2nd edition that adds the support for multiple data stream files, and is available from http://www.ecma.ch. The previous edition of ECMA 167 (2nd) was is equivalent to ISO/IEC 13346:1995. References enclosed in [ ] in this document are references to ECMA 167 3rd edition. The references are in the form [x/a.b.c], where x is the section number and a.b.c is the paragraph or figure number.

1.3.2 Definitions

Audio session Audio session contains one or more audio tracks, and no data track.

Audio track Audio tracks are tracks that are designated to contain audio sectors specified in ISO/IEC 908.

CD-R CD-Recordable. A write once CD defined in Orange Book, part-II.

CD-RW CD-Rewritable. An overwritable CD defined in Orange Book, part-III.

Clean File System The file system on the media conforms to this specification.

Data track Data tracks are tracks that are designated to contain data sectors specified in ISO/IEC 10149.

Dirty File System A file system that is not a clean file system.

Fixed Packet An incremental recording method in which all packets in a given track are of a length specified in the Track Descriptor Block. Addresses presented to a CD drive are translated according to the Method 2 addressing specified in Orange Book parts-II and -III.

ICB A control node in ECMA 167.

Logical Block Address A logical block number [3/8.8.1].

NOTE 1: This is not to be confused with a logical block address [4/7.1], given by the lb_addr structure which contains both a logical block number [3/8.8.1] and a partition reference number [3/8.8], the latter identifying the partition [3/8.7] which contains the addressed logical block [3/8.8.1].

Media Block Address
A sector number [3/8.1.1], derived from the unique sector address given by a relevant standard for recording [1/5.10]. In this specification, a sector number [3/8.1.1] is equivalent to a logical sector number [3/8.1.2].

Packet
A recordable unit, which is an integer number of contiguous sectors [1/5.9], which consist of user data sectors, and may include additional sectors [1/5.9] which are recorded as overhead of the Packet-writing operation and are addressable according to the relevant standard for recording [1/5.10].

Physical Address
A sector number [3/8.1.1], derived from the unique sector address given by a relevant standard for recording [1/5.10]. In this specification, a sector number [3/8.1.1] is equivalent to a logical sector number [3/8.1.2].

Physical Block Address
A sector number [3/8.1.1], derived from the unique sector address given by a relevant standard for recording [1/5.10]. In this specification, a sector number [3/8.1.1] is equivalent to a logical sector number [3/8.1.2].

physical sector
A sector [1/5.9] given by a relevant standard for recording [1/5.10]. In this specification, a sector [1/5.9] is equivalent to a logical sector [3/8.1.2].

Random Access File System
A file system for randomly writable media, either write once or rewritable.

Sequential File System
A file system for sequentially written media (e.g. CD-R)

Session
The tracks of a volume shall be organized into one or more sessions as specified by the Orange Book part-II. A session shall be a sequence of one or more tracks, the track numbers of which form a contiguous ascending sequence.

Track
The sectors of a volume shall be organized into one or more tracks. A track shall be a sequence of sectors, the sector numbers of which form a contiguous ascending sequence. No sector shall belong to more than one track.

Note: There may be gaps between tracks; that is, the last sector of a track need not be adjacent to the first sector of the next track.

UDF
OSTA Universal Disk Format

user data blocks
The logical blocks [3/8.8.1] which were recorded in the sectors [1/5.9] (equivalent in this specification to logical sectors [3/8.1.2]) of a Packet and which contain the data intentionally recorded by the user of the drive. This specifically does not include the logical blocks [3/8.8.1], if any, whose constituent sectors [1/5.9] were used for the overhead of recording the Packet, even though those sectors [1/5.9] are addressable according to the relevant standard for recording [1/5.10]. Like any logical blocks [3/8.8.1], user data blocks are identified by logical block numbers [3/8.8.1].
user data sectors: The sectors [1/5.9] of a Packet which contain the data intentionally recorded by the user of the drive, specifically not including those sectors [1/5.9] used for the overhead of recording the Packet, even though those sectors [1/5.9] may be addressable according to the relevant standard for recording [1/5.10]. Like any sectors [1/5.9], user data sectors are identified by sector numbers [3/8.1.1]. In this specification, a sector number [3/8.1.1] is equivalent to a a logical sector number [3/8.1.2].

Variable Packet: An incremental recording method in which each packet in a given track is of a host determined length. Addresses presented to a CD drive are as specified in Method 1 addressing in Orange Book parts II and III.

VAT ICB: A File Entry ICB that describes a file containing a Virtual Allocation Table.

1.3.3 Terms

May: Indicates an action or feature that is optional.

Optional: Describes a feature that may or may not be implemented. If implemented, the feature shall be implemented as described.

Shall: Indicates an action or feature that is mandatory and must be implemented to claim compliance to this standard.

Should: Indicates an action or feature that is optional, but its implementation is strongly recommended.
Reserved

A reserved field is reserved for future use and shall be set to zero. A reserved value is reserved for future use and shall not be used.

2. Basic Restrictions & Requirements

The following table summarizes several of the basic restrictions and requirements defined in this specification. These restrictions & requirements as well as additional ones are described in detail in the following sections of this specification.

<table>
<thead>
<tr>
<th>Item</th>
<th>Restrictions &amp; Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logical Sector Size</td>
<td>The <em>Logical Sector Size</em> for a specific volume shall be the same as the physical sector size of the specific volume.</td>
</tr>
<tr>
<td>Logical Block Size</td>
<td>The <em>Logical Block Size</em> for a Logical Volume shall be set to the logical sector size of the volume or volume set on which the specific logical volume resides.</td>
</tr>
<tr>
<td>Volume Sets</td>
<td>All media within the same Volume Set shall have the same physical sector size. Rewritable/Overwritable media and WORM media shall not be mixed in/ be present in the same volume set.</td>
</tr>
<tr>
<td>First 32K of Volume Space</td>
<td>The first 32768 bytes of the Volume space shall not be used for the recording of ECMA 167 structures. This area shall not be referenced by the Unallocated Space Descriptor or any other ECMA 167 descriptor. This is intended for use by the native operating system.</td>
</tr>
<tr>
<td>Volume Recognition Sequence</td>
<td>The Volume Recognition Sequence as described in part 2 of ECMA 167 shall be recorded.</td>
</tr>
<tr>
<td>Timestamp</td>
<td>All timestamps shall be recorded in local time. Time zones shall be recorded on operating systems that support the concept of a time zone.</td>
</tr>
<tr>
<td>Entity Identifiers</td>
<td>Entity Identifiers shall be recorded in accordance with this document. Unless otherwise specified in this specification the Entity Identifiers shall contain a value that uniquely identifies the implementation.</td>
</tr>
<tr>
<td>Descriptor CRCs</td>
<td>CRCs shall be supported and calculated for all Descriptors, except for the Space Bitmap Descriptor.</td>
</tr>
<tr>
<td>File Name Length</td>
<td>Maximum of 255 bytes</td>
</tr>
<tr>
<td>Extent Length</td>
<td>Maximum Extent Length shall be $2^{30} - 1$ rounded down to the nearest integral multiple of the Logical Block Size. Maximum Extent Length for extents in virtual space shall be the Logical Block Size.</td>
</tr>
<tr>
<td>Primary Volume Descriptor</td>
<td>There shall be exactly one prevailing Primary Volume Descriptor recorded per volume. The media where the <em>VolumeSequenceNumber</em> of this descriptor is equal to 1 (one) must be part of the logical volume defined by the prevailing Logical Volume Descriptor.</td>
</tr>
<tr>
<td>Anchor Volume Descriptor Pointer</td>
<td>Shall be recorded in at least 2 of the following 3 locations: 256, N-256, or N, where N is the last addressable sector of a volume. See also 2.2.3.</td>
</tr>
</tbody>
</table>
| Partition Descriptor        | A Partition Descriptor Access Type of Read-Only, Rewritable, Overwritable and WORM shall be supported. There shall be exactly one prevailing Partition Descriptor recorded per volume, with one exception. For Volume Sets that consist of single volume, the volume may contain 2.
Partitions with 2 prevailing Partition Descriptors only if one has an access type of read only and the other has an access type of Rewritable, Overwritable, or WORM. The Logical Volume for this volume would consist of the contents of both partitions.

| Logical Volume Descriptor | There shall be exactly one prevailing Logical Volume Descriptor recorded per Volume Set. The **LogicalVolumeIdentifier** field shall not be null and should contain an identifier that aids in the identification of the logical volume. Specifically, software generating volumes conforming to this specification shall not set this field to a fixed or trivial value. Duplicate disks, which are intended to be identical, may contain the same value in this field. This field is extremely important in logical volume identification when multiple media are present within a jukebox. This name is typically what is displayed to the user. The **LogicalVolumeDescriptor** recorded on the volume where the **PrimaryVolumeDescriptor's VolumeSequenceNumber** field is equal to 1 (one) must have a **NumberOfPartitionMaps** value and **PartitionMaps** structure(s) that represent the entire logical volume. For example, if a volume set is extended by adding partitions, then the updated **LogicalVolumeDescriptor** written to the last volume in the set must also be written (or rewritten) to the first volume of the set. |
| Logical Volume Integrity Descriptor | Shall be recorded. The extent of LVIDs may be terminated by the extent length. |
| Unallocated Space Descriptor | A single prevailing Unallocated Space Descriptor shall be recorded per volume. |
| File Set Descriptor | There shall be exactly one File Set Descriptor recorded per Logical Volume on Rewritable/Overwritable media. For WORM media multiple File Set Descriptors may be recorded based upon certain restrictions defined in this document. The FSD extent may be terminated by the extent length. |
| ICB Tag | Only strategy types 4 or 4096 shall be recorded. |
| File Identifier Descriptor | The total length of a **File Identifier Descriptor** shall not exceed the size of one Logical Block. |
| File Entry | The total length of a **File Entry** shall not exceed the size of one Logical Block. |
| Allocation Descriptors | Only Short and Long Allocation Descriptors shall be recorded. |
| Allocation Extent Descriptors | The length of any single extent of allocation descriptors shall not exceed the **Logical Block Size**. |
| Unallocated Space Entry | The total length of an **Unallocated Space Entry** shall not exceed the size of one Logical Block. |
| Space Bitmap Descriptor | **CRC not required.** |
| Partition Integrity Entry | Shall not be recorded. |
| Volume Descriptor Sequence Extent | Both the main and reserve volume descriptor sequence extents shall each have a minimum length of 16 logical sectors. The VDS Extent may be terminated by the extent length. |
| Record Structure | Record structure files, as defined in part 5 of ECMA 167, shall not be created. |
2.1 Part 1 - General
2.1.1 Character Sets

The character set used by UDF for the structures defined in this document is the CS0 character set. The OSTA CS0 character set is defined as follows:

OSTA CS0 shall consist of the d-characters specified in The Unicode Standard, Version 2.0 (ISBN 0-201-48345-9 from Addison-Wesley Publishing Company http://www.awl.com/, see also http://www.unicode.org), excluding #FEFF and FFFE, stored in the OSTA Compressed Unicode format which is defined as follows:

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Compression ID</td>
<td>Uint8</td>
</tr>
<tr>
<td>1</td>
<td>??</td>
<td>Compressed Bit Stream</td>
<td>Byte</td>
</tr>
</tbody>
</table>

The CompressionID shall identify the compression algorithm used to compress the CompressedBitStream field. The following algorithms are currently supported:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 7</td>
<td>Reserved</td>
</tr>
<tr>
<td>8</td>
<td>Value indicates there are 8 bits per character in the CompressedBitStream.</td>
</tr>
<tr>
<td>9-15</td>
<td>Reserved</td>
</tr>
<tr>
<td>16</td>
<td>Value indicates there are 16 bits per character in the CompressedBitStream.</td>
</tr>
<tr>
<td>17-253</td>
<td>Reserved</td>
</tr>
<tr>
<td>254</td>
<td>Value indicates the CS0 expansion is empty and unique. Compression Algorithm 8 is used for compression.</td>
</tr>
<tr>
<td>255</td>
<td>Value indicates the CS0 expansion is empty and unique. Compression Algorithm 16 is used for compression.</td>
</tr>
</tbody>
</table>

For a CompressionID of 8 or 16, the value of the CompressionID shall specify the number of BitsPerCharacter for the d-characters defined in the CharacterBitStream field. Each sequence of CompressionID bits in the CharacterBitStream field shall represent an OSTA Compressed Unicode d-character. The bits of the character being encoded shall be added to the CharacterBitStream from most- to least-significant-bit. The bits shall be added to the CharacterBitStream starting from the most significant bit of the current byte being encoded into.
NOTE: This encoding causes characters written with a CompressionID of 16 to be effectively written in big endian format.

The value of the OSTA Compressed Unicode d-character interpreted as a Uint16 defines the value of the corresponding d-character in the Unicode 2.0 standard. Refer to appendix on OSTA Compressed Unicode for sample C source code to convert between OSTA Compressed Unicode and standard Unicode 2.0.

The Unicode byte-order marks, #FEFF and #FFFF, shall not be used.

Compression IDs 254 and 255 shall only be used in FIDs where the deleted bit is set to ONE.

When uncompressing file identifiers with Compression IDs 254 and 255, the resulting name is to be considered empty and unique.

2.1.2 OSTA CS0 Charspec

```c
struct charspec { /* ECMA 167 1/7.2.1 */
    Uint8 CharacterSetType;
    byte CharacterSetInfo[63];
}
```

The CharacterSetType field shall have the value of 0 to indicate the CS0 coded character set.

The CharacterSetInfo field shall contain the following byte values with the remainder of the field set to a value of 0.

```
#4F, #53, #54, #41, #20, #43, #6F, #6D, #70, #72, #65, #73, #73, #64, #20, #55, #6E, #69, #63, #6F, #64, #65
```

The above byte values represent the following ASCII string:

“OSTA Compressed Unicode”

2.1.3 Dstrings

The ECMA 167 standard, as well as this document, has normally defined byte positions relative to 0. In section 7.2.12 of ECMA 167, dstrings are defined in terms of being relative to 1. Since this offers an opportunity for confusion, the following shows what the definition would be if described relative to 0.

7.2.12 Fixed-length character fields
A dstring of length \( n \) is a field of \( n \) bytes where d-characters (1/7.2) are recorded. The number of bytes used to record the characters shall be recorded as a Uint8 (1/7.1.1) in byte \( n-1 \), where \( n \) is the length of the field. The characters shall be recorded starting with the first byte of the field, and any remaining byte positions after the characters up until byte \( n-2 \) inclusive shall be set to #00.

If the number of d-characters to be encoded is zero, the length of the dstring shall be zero.

NOTE: The length of a dstring includes the compression code byte (2.1.1) except for the case of a zero length string. A zero length string shall be recorded by setting the entire dstring field to all zeros.

2.1.4 Timestamp

```c
struct timestamp { /* ECMA 167 1/7.3 */
    Uint16    TypeAndTimezone;
    Uint16    Year;
    Uint8     Month;
    Uint8     Day;
    Uint8     Hour;
    Uint8     Minute;
    Uint8     Second;
    Uint8     Centiseconds;
    Uint8     HundredsofMicroseconds;
    Uint8     Microseconds;
}
```

2.1.4.1 Uint16 TypeAndTimezone;

For the following descriptions \( Type \) refers to the most significant 4 bits of this field, and \( TimeZone \) refers to the least significant 12 bits of this field, which is interpreted as a signed 12-bit number in two’s complement form.

- The time within the structure shall be interpreted as Local Time since \( Type \) shall be equal to ONE for OSTA UDF compliant media.
- \( Type \) shall be set to ONE to indicate Local Time.
- \( TimeZone \) shall be interpreted as specifying the time zone for the location when this field was last modified. If this field contains -2047 then the time zone has not been specified.
- For operating systems that support the concept of a time zone, the offset of the time zone (in 1 minute increments), from Coordinated Universal Time, shall be inserted in the \( TimeZone \) field. Otherwise the \( TimeZone \) shall be set to –2047.
Note: Time zones West of Coordinated Universal Time have negative offsets. For example, Eastern Standard Time is -300 minutes; Eastern Daylight Time is -240 minutes.

Note: Implementations on systems that support time zones should interpret unspecified time zones as Coordinated Universal Time. Although not a requirement, this interpretation has the advantage that files generated on systems that do not support time zones will always appear to have the same time stamps on systems that do support time zones, irrespective of the interpreting system's local time zone.

2.1.5 Entity Identifier

```c
struct EntityID { /* ECMA 167 1/7.4 */
    Uint8 Flags;
    char Identifier[23];
    char IdentifierSuffix[8];
}
```

UDF classifies Entity Identifiers into 4 separate types as follows:

- Domain Entity Identifiers
- UDF Entity Identifiers
- Implementation Entity Identifiers
- Application Entity Identifiers

The following sections describe the format and use of Entity Identifiers based upon the different types mentioned above.

2.1.5.1 Uint8 Flags

ournaments Self-explanatory.

Shall be set to ZERO.

2.1.5.2 char Identifier

Unless stated otherwise in this document this field shall be set to an identifier that uniquely identifies the implementation. This methodology will allow for identification of the implementation responsible for creating structures recorded on media interchanged between different implementations.
If an implementation updates existing structures on the media written by other implementations the updating implementation shall set the Identifier field to a value that uniquely identifies the updating implementation.

The following table summarizes the Entity Identifier fields defined in the ECMA 167 standard and this document and shows to what values they shall be set.

<table>
<thead>
<tr>
<th>Entity Identifiers</th>
</tr>
</thead>
<tbody>
<tr>
<td>Descriptor</td>
</tr>
<tr>
<td>Primary Volume Descriptor</td>
</tr>
<tr>
<td>Primary Volume Descriptor</td>
</tr>
<tr>
<td>Implementation Use Volume Descriptor</td>
</tr>
<tr>
<td>Implementation Use Volume Descriptor</td>
</tr>
<tr>
<td>Partition Descriptor</td>
</tr>
<tr>
<td>Partition Descriptor</td>
</tr>
<tr>
<td>Logical Volume Descriptor</td>
</tr>
<tr>
<td>Logical Volume Descriptor</td>
</tr>
<tr>
<td>File Set Descriptor</td>
</tr>
<tr>
<td>File Identifier Descriptor</td>
</tr>
<tr>
<td>File Entry</td>
</tr>
<tr>
<td>Device Specification Extended Attribute</td>
</tr>
<tr>
<td>UDF Implementation Use Extended Attribute</td>
</tr>
<tr>
<td>Non-UDF Implementation Use Extended Attribute</td>
</tr>
<tr>
<td>UDF Application Use Extended Attribute</td>
</tr>
<tr>
<td>Non-UDF Application Use Extended Attribute</td>
</tr>
<tr>
<td>UDF Unique ID Mapping Data</td>
</tr>
<tr>
<td>Power Calibration Table Stream</td>
</tr>
<tr>
<td>Logical Volume Integrity Descriptor</td>
</tr>
<tr>
<td>------------------------------------</td>
</tr>
<tr>
<td>Partition Integrity Entry</td>
</tr>
<tr>
<td>Virtual Partition Map</td>
</tr>
<tr>
<td>Virtual Allocation Table</td>
</tr>
<tr>
<td>Sparable Partition Map</td>
</tr>
<tr>
<td>Sparing Table</td>
</tr>
</tbody>
</table>

**NOTE:** The value of the Entity Identifier field is interpreted as a sequence of bytes, and not as a dstring specified in CS0. For ease of use the values used by UDF for this field are specified in terms of ASCII character strings. The actual sequence of bytes used for the Entity Identifiers defined by UDF are specified in section 6.2.

**NOTE:** In the ID Value column in the above table "*Application ID" refers to an identifier that uniquely identifies the writer’s application.

In the ID Value column in the above table "*Developer ID" refers to an Entity Identifier that uniquely identifies the current implementation. The value specified should be used when a new descriptor is created. Also, the value specified should be used for an existing descriptor when anything within the scope of the specified EntityID field is modified.

**NOTE:** The value chosen for a "*Developer ID" should contain enough information to identify the company and product name for an implementation. For example, a company called XYZ with a UDF product called DataOne might choose "*XYZ DataOne" as their developer ID. Also in the suffix of their developer ID they may choose to record the current version number of their DataOne product. This information is extremely helpful when trying to determine which implementation wrote a bad structure on a piece of media when multiple products from different companies have been recording on the media.

The Suffix Type column in the above table defines the format of the suffix to be used with the corresponding Entity Identifier. These different suffix types are defined in the following paragraphs.

**NOTE:** All Identifiers defined in this document (appendix 6.1) shall be registered by OSTA as UDF Identifiers.
2.1.5.3 IdentifierSuffix

The format of the IdentifierSuffix field is dependent on the type of the Identifier.

In regard to OSTA Domain Entity Identifiers specified in this document (appendix 6.1) the IdentifierSuffix field shall be constructed as follows:

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>UDF Revision</td>
<td>Uint16 (= #0201)</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>Domain Flags</td>
<td>Uint8</td>
</tr>
<tr>
<td>3</td>
<td>5</td>
<td>Reserved</td>
<td>bytes (= #00)</td>
</tr>
</tbody>
</table>

The UDFRevision field shall contain #0201 to indicate revision 2.01 of this document. This field will allow an implementation to detect changes made in newer revisions of this document. The OSTA Domain Identifiers are only used in the Logical Volume Descriptor and the File Set Descriptor. The DomainFlags field defines the following bit flags:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Hard Write-Protect</td>
</tr>
<tr>
<td>1</td>
<td>Soft Write-Protect</td>
</tr>
<tr>
<td>2-7</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

The SoftWriteProtect flag is a user settable flag that indicates that the volume or file system structures within the scope of the descriptor in which it resides are write protected. A SoftWriteProtect flag value of ONE shall indicate user write protected structures. This flag may be set or reset by the user. The HardWriteProtect flag is an implementation settable flag that indicates that the scope of the descriptor in which it resides is permanently write protected. A HardWriteProtect flag value of ONE shall indicate a permanently write protected structure. Once set this flag shall not be reset. The HardWriteProtect flag overrides the SoftWriteProtect flag.

The write protect flags appear in the Logical Volume Descriptor and in the File Set Descriptor. They shall be interpreted as follows:

is_fileset_write_protected = LVD.HardWriteProtect || LVD.SoftWriteProtect || FSD.HardWriteProtect || FSD.SoftWriteProtect
is_fileset_hard_protected = LVD.HardWriteProtect || FSD.HardWriteProtect
is_fileset_soft_protected = (LVD.SoftWriteProtect || FSD.SoftWriteProtect) && (! is_vol_hard_protected)
is_vol_write_protected = LVD.HardWriteProtect || LVD.SoftWriteProtect
is_vol_hard_protected = LVD.HardWriteProtect
is_vol_soft_protected = LVD.SoftWriteProtect && !LVD.HardWriteProtect

Implementation use *Entity Identifiers* defined by UDF (appendix 6.1) the *IdentifierSuffix* field shall be constructed as follows:

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>UDF Revision</td>
<td>Uint16 (= #0201)</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>OS Class</td>
<td>Uint8</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>OS Identifier</td>
<td>Uint8</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Reserved</td>
<td>bytes (= #00)</td>
</tr>
</tbody>
</table>

The contents of the *OS Class* and *OS Identifier* fields are described in the Appendix on *Operating System Identifiers*. For implementation use *Entity Identifiers* not defined by UDF the *IdentifierSuffix* field shall be constructed as follows:

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>OS Class</td>
<td>Uint8</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>OS Identifier</td>
<td>Uint8</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
<td>Implementation Use Area</td>
<td>bytes</td>
</tr>
</tbody>
</table>

**NOTE:** It is important to understand the intended use and importance of the *OS Class* and *OS Identifier* fields. The main purpose of these fields is to aid in debugging when problems are found on a UDF volume. The fields also provide useful information that could be provided to the end user. When set correctly these two fields provide an implementation with information such as the following:

- Identify under which operating system a particular structure was last modified.
- Identify under which operating system a specific file or directory was last modified.
- If a developer supports multiple operating systems with their implementation, it helps to determine under which operating system a problem may have occurred.

For an *Application Entity Identifier* not defined by UDF, the *IdentifierSuffix* field shall be constructed as follows, unless specified otherwise.

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>Implementation Use Area</td>
<td>bytes</td>
</tr>
</tbody>
</table>
2.1.6 Descriptor Tag Serial Number at Formatting Time

In order to support disaster recovery, the TagSerialNumber value of all UDF descriptors that will be recorded at formatting time, shall be set to a value that differs from ones previously recorded, upon volume re-initialization.

If no disaster recovery will be supported, a value zero (#0000) shall be used for the TagSerialNumber field of all UDF descriptors that will be recorded at formatting time, see ECMA 3/7.2.5 and 4/7.2.5.

If disaster recovery is supported, the value to be used depends on the state of the volume prior to formatting. There are only two states in which a volume can be formatted such that disaster recovery will be possible in the future. These states are:

1) The volume is completely erased. Only after this action, and where disaster recovery is to be supported then a value of one (#0001) shall be used as the TagSerialNumber value.

2) The volume is a clean UDF volume that supports disaster recovery for TagSerialNumber values, and the TagSerialNumber values of at least two Anchor Volume Descriptor Pointers are both equal to X, where X is not equal to zero. If disaster recovery is to be supported then a value X+1 shall be used as the TagSerialNumber value. If X+1 wraps to zero then keep it as zero to indicate that disaster recovery is not supported.

NOTE: The reason for this is that if X+1 wraps to zero then the uniqueness of any TagSerialNumber value unequal to zero can no longer be guaranteed on the volume.

NOTE: By ‘erased’ in the above paragraphs, we mean that the sectors are made non-valid for UDF – for example by writing zeroes to the sectors.

2.1.7 Volume Recognition Sequence

The following rules shall apply when writing the volume recognition sequence:

- The Volume Recognition Sequence (VRS) as described in part 2 and part 3 of ECMA 167 shall be recorded. There shall be exactly one NSR descriptor in the VRS. The NSR and BOOT2 descriptors shall be in the Extended Area. There shall be only one Extended Area with one BEA01 and one TEA01. All other VSDs are only allowed before the Extended Area. The block after the VRS shall be unrecorded or contain all #00.

- Implementers should expect that disks recorded by UDF 2.00 and earlier did not have this constraint, and should handle these cases accordingly.
### 2.2 Part 3 - Volume Structure

#### 2.2.1 Descriptor Tag

```c
struct tag {
    /* ECMA 167 3/7.2 */
    Uint16 TagIdentifier;
    Uint16 DescriptorVersion;
    Uint8  TagChecksum;
    byte   Reserved;
    Uint16 TagSerialNumber;
    Uint16 DescriptorCRC;
    Uint16 DescriptorCRCLength;
    Uint32 TagLocation;
}
```

#### 2.2.1.1 Uint16 TagSerialNumber

- Ignored. Intended for disaster recovery.
- Shall be set to the `TagSerialNumber` value of the Anchor Volume Descriptor Pointers on this volume.

In order to preserve disaster recovery support, the `TagSerialNumber` must be set to a value that differs from ones previously recorded, upon volume re-initialization. This value is determined at volume formatting time and may depend on the state of the volume prior to formatting. See 2.1.6 for further details.

#### 2.2.1.2 Uint16 DescriptorCRCLength

CRCs shall be supported and calculated for each descriptor. The value of this field shall be set to (Size of the Descriptor) - (Length of Descriptor Tag). When reading a descriptor the CRC should be validated.

**NOTE:** The `DescriptorCRCLength` field must not be used to determine the actual length of the descriptor or the number of bytes to read. These lengths do not match in all cases; there are exceptions in the standard where the Descriptor CRC Length need not match the length of the descriptor.
2.2.2 Primary Volume Descriptor

struct PrimaryVolumeDescriptor { /* ECMA 167 3/10.1 */
    struct tag DescriptorTag;
    Uint32 VolumeDescriptorSequenceNumber;
    Uint32 PrimaryVolumeDescriptorNumber;
    dstring VolumeIdentifier[32];
    Uint16 VolumeSequenceNumber;
    Uint16 MaximumVolumeSequenceNumber;
    Uint16 InterchangeLevel;
    Uint16 MaximumInterchangeLevel;
    Uint32 CharacterSetList;
    Uint32 MaximumCharacterSetList;
    dstring VolumeSetIdentifier[128];
    struct charspec DescriptorCharacterSet;
    struct charspec ExplanatoryCharacterSet;
    struct extent_ad VolumeAbstract;
    struct extent_ad VolumeCopyrightNotice;
    struct EntityID ApplicationIdentifier;
    struct timestamp RecordingDateandTime;
    struct EntityID ImplementationIdentifier;
    byte ImplementationUse[64];
    Uint32 PredecessorVolumeDescriptorSequenceLocation;
    Uint16 Flags;
    byte Reserved[22];
}

2.2.2.1 Uint16 InterchangeLevel

Interpreted as specifying the current interchange level (as specified in ECMA 167 3/11), of the contents of the associated volume and the restrictions implied by the specified level.

If this volume is part of a multi-volume Volume Set then the level shall be set to 3, otherwise the level shall be set to 2.

ECMA 167 requires an implementation to enforce the restrictions associated with the specified current Interchange Level. The implementation may change the value of this field as long as it does not exceed the value of the Maximum Interchange Level field.

2.2.2.2 Uint16 MaximumInterchangeLevel

Interpreted as specifying the maximum interchange level (as specified in ECMA 167 3/11), of the contents of the associated volume.
This field shall be set to level 3 (No Restrictions Apply), unless specifically given a different value by the user.

**NOTE:** This field is used to determine the intent of the originator of the volume. If this field has been set to 2 then the originator does not wish the volume to be included in a multi-volume set (interchange level 3). The receiver may override this field and set it to a 3 but the implementation should give the receiver a strict warning explaining the intent of the originator of the volume.

### 2.2.2.3 Uint32 CharacterSetList

- Interpreted as specifying the character set(s) in use by any of the structures defined in Part 3 of ECMA 167 (3/10.1.9).
- Shall be set to indicate support for CS0 only as defined in 2.1.2.

### 2.2.2.4 Uint32 MaximumCharacterSetList

- Interpreted as specifying the maximum supported character sets (as specified in ECMA 167) which may be specified in the `CharacterSetList` field.
- Shall be set to indicate support for CS0 only as defined in 2.1.2.

### 2.2.2.5 dstring VolumeSetIdentifier

- Interpreted as specifying the identifier for the volume set.
- The first 16 characters of this field should be set to a unique value. The remainder of the field may be set to any allowed value. Specifically, software generating volumes conforming to this specification shall not set this field to a fixed or trivial value. Duplicate disks which are intended to be identical may contain the same value in this field.

**NOTE:** The intended purpose of this is to guarantee Volume Sets with unique identifiers. The first 8 characters of the unique part should come from a CS0 hexadecimal representation of a 32-bit time value. The remaining 8 characters are free for implementation use.

### 2.2.2.6 struct charspec DescriptorCharacterSet

- Interpreted as specifying the character sets allowed in the `Volume Identifier` and `Volume Set Identifier` fields.
- Shall be set to indicate support for CS0 as defined in 2.1.2.
2.2.2.7 struct charspec ExplanatoryCharacterSet

Interpreted as specifying the character sets used to interpret the contents of the VolumeAbstract and VolumeCopyrightNotice extents.

Shall be set to indicate support for CS0 as defined in 2.1.2.

2.2.2.8 struct EntityID ImplementationIdentifier

For more information on the proper handling of this field see section 2.1.5.

2.2.2.9 struct EntityID ApplicationIdentifier

This field either specifies a valid Entity Identifier (section 2.1.5) identifying the application that last wrote this field, or the field is filled with all #00 bytes, meaning that no application is identified.

Either all #00 bytes or a valid Entity Identifier (section 2.1.5) shall be recorded in this field.

2.2.3 Anchor Volume Descriptor Pointer

struct AnchorVolumeDescriptorPointer {
  struct DescriptorTag; /* ECMA 167 3/10.2 */
  struct extent_ad MainVolumeDescriptorSequenceExtent;
  struct extent_ad ReserveVolumeDescriptorSequenceExtent;
  byte Reserved[480];
}

NOTE: An AnchorVolumeDescriptorPointer structure shall be recorded in at least 2 of the following 3 locations on the media:

- Logical Sector 256.
- Logical Sector (N - 256).
- N

NOTE: As specified in section 6.10, unclosed CD-R media may have a single AVDP present at either sector 256 or 512. If on an unclosed disc a single AVDP is recorded on sector 256, any AVDP recorded on sector 512 must be ignored. Closed CD-R media shall conform to the above rules.

2.2.3.1 struct MainVolumeDescriptorSequenceExtent

The main VolumeDescriptorSequenceExtent shall have a minimum length of 16 logical sectors.
2.2.3.2  **struct ReserveVolumeDescriptorSequenceExtent**

The reserve *VolumeDescriptorSequenceExtent* shall have a minimum length of 16 logical sectors.

2.2.4  **Logical Volume Descriptor**

```c
struct LogicalVolumeDescriptor { /* ECMA 167 3/10.6 */
    struct tag      DescriptorTag;
    Uint32          VolumeDescriptorSequenceNumber;
    struct charspec DescriptorCharacterSet;
    dstring         LogicalVolumeIdentifier[128];
    Uint32          LogicalBlockSize,
    struct EntityID DomainIdentifier;
    byte            LogicalVolumeContentsUse[16];
    Uint32          MapTableLength;
    Uint32          NumberofPartitionMaps;
    struct EntityID ImplementationIdentifier;
    byte            ImplementationUse[128];
    extent_ad      IntegritySequenceExtent,
    byte            PartitionMaps[];
}
```

2.2.4.1  **struct charspec DescriptorCharacterSet**

- Interpreted as specifying the character set allowed in the *LogicalVolumeIdentifier* field.
- Shall be set to indicate support for CS0 as defined in 2.1.2.

2.2.4.2  **Uint32 LogicalBlockSize**

- Interpreted as specifying the *Logical Block Size* for the logical volume identified by this *LogicalVolumeDescriptor*.
- This field shall be set to the largest logical sector size encountered amongst all the partitions on media that constitute the logical volume identified by this *LogicalVolumeDescriptor*. Since UDF requires that all Volumes within a VolumeSet have the same logical sector size, the *Logical Block Size* will be the same as the logical sector size of the Volume.

2.2.4.3  **struct EntityID DomainIdentifier**

- Interpreted as specifying a domain specifying rules on the use of, and restrictions on, certain fields in the descriptors. If this field is all zero then it is ignored, otherwise the *Entity Identifier* rules are followed. **NOTE:** If the field
does not contain "*OSTA UDF Compliant" then an implementation may deny
the user access to the logical volume.

This field shall indicate that the contents of this logical volume conforms to the
domain defined in this document, therefore the DomainIdentifier shall be set
to:

"*OSTA UDF Compliant"

As described in the section on Entity Identifier the IdentifierSuffix field of this
EntityID shall contain the revision of this document for which the contents of
the Logical Volume is compatible. For more information on the proper handling
of this field see section 2.1.5.

NOTE: The IdentifierSuffix field of this EntityID contains SoftWriteProtect
and HardWriteProtect flags. Refer to 2.1.5.3.

2.2.4.4 byte LogicalVolumeContentUse[16]

This field contains the extent location of the FileSet Descriptor. This is described in 4/3.1 of
ECMA 167 as follows:

“If the volume is recorded according to Part 3, the extent in which the first File Set Descriptor
Sequence of the logical volume is recorded shall be identified by a long_ad (4/14.14.2) recorded
in the Logical Volume Contents Use field (see 3/10.6.7) of the Logical Volume Descriptor
describing the logical volume in which the File Set Descriptors are recorded.”

This field can be used to find the FileSet descriptor, and from the FileSet descriptor the root
volume can be found.

2.2.4.5 struct EntityID ImplementationIdentifier;

For more information on the proper handling of this field see section 2.1.5.

2.2.4.6 struct extent_ad IntegritySequenceExtent

A value in this field is required for the Logical Volume Integrity Descriptor. For
Rewriteable or Overwriteable media this shall be set to a minimum of 8K bytes.

WARNING: For WORM media this field should be set to an extent of some
substantial length. Once the WORM volume on which the Logical Volume Integrity
Descriptor resides is full a new volume must be added to the volume set since the
Logical Volume Integrity Descriptor must reside on the same volume as the prevailing
Logical Volume Descriptor.
2.2.4.7 byte PartitionMaps
For the purpose of interchange partition maps shall be limited to Partition Map type 1, except type 2 maps as described in this document (2.2.8 and 2.2.9).

2.2.5 Unallocated Space Descriptor
struct UnallocatedSpaceDesc { /* ECMA 167 3/10.8 */
    struct tag DescriptorTag;
    Uint32 VolumeDescriptorSequenceNumber;
    Uint32 NumberOfAllocationDescriptors;
    extent_ad AllocationDescriptors[];
}

This descriptor shall be recorded, even if there is no free volume space. The first 32768 bytes of the Volume space shall not be used for the recording of ECMA 167 structures. This area shall not be referenced by the Unallocated Space Descriptor or any other ECMA 167 descriptor.

2.2.6 Logical Volume Integrity Descriptor
struct LogicalVolumeIntegrityDesc { /* ECMA 167 3/10.10 */
    struct tag DescriptorTag,
    Timestamp RecordingDateAndTime,
    Uint32 IntegrityType,
    struct extend_ad NextIntegrityExtent,
    byte LogicalVolumeContentsUse[32],
    Uint32 NumberOfPartitions,
    Uint32 LengthOfImplementationUse,
    Uint32 FreeSpaceTable [],
    Uint32 SizeTable [],
    byte ImplementationUse[]
}

The Logical Volume Integrity Descriptor is a structure that shall be written any time the contents of the associated Logical Volume is modified. Through the contents of the Logical Volume Integrity Descriptor an implementation can easily answer the following useful questions:

1) Are the contents of the Logical Volume in a consistent state?

2) When was the last date and time that anything within the Logical Volume was modified?

3) What is the total Logical Volume free space in logical blocks?
4) What is the total size of the Logical Volume in logical blocks?

5) What is the next available UniqueID for use within the Logical Volume?

6) Has some other implementation modified the contents of the logical volume since the last time that the original implementation, which created the logical volume, accessed it.

2.2.6.1 byte LogicalVolumeContentsUse
See section 3.2.1 for information on the contents of this field.

2.2.6.2 Uint32 FreeSpaceTable
Since most operating systems require that an implementation provide the true free space of a Logical Volume at mount time it is important that these values be maintained for all non-virtual partitions. The optional value of #FFFFFFFF, which indicates that the amount of available free space is not known, shall not be used for non-virtual partitions. For virtual partitions the FreeSpaceTable shall be set to #FFFFFFFF.

NOTE: The FreeSpaceTable is guaranteed to be correct only when the Logical Volume Integrity Descriptor is closed.

2.2.6.3 Uint32 SizeTable
Since most operating systems require that an implementation provide the total size of a Logical Volume at mount time it is important that these values be maintained for all non-virtual partitions. The optional value of #FFFFFFFF, which indicates that the partition size is not known, shall not be used for non-virtual partitions. For virtual partitions the SizeTable shall be set to #FFFFFFFF.

2.2.6.4 byte ImplementationUse
The ImplementationUse area for the Logical Volume Integrity Descriptor shall be structured as follows:

```
<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>32</td>
<td>ImplementationID</td>
<td>EntityID</td>
</tr>
<tr>
<td>32</td>
<td>4</td>
<td>Number of Files</td>
<td>Uint32</td>
</tr>
<tr>
<td>36</td>
<td>4</td>
<td>Number of Directories</td>
<td>Uint32</td>
</tr>
<tr>
<td>40</td>
<td>2</td>
<td>Minimum UDF Read Revision</td>
<td>Uint16</td>
</tr>
<tr>
<td>42</td>
<td>2</td>
<td>Minimum UDF Write Revision</td>
<td>Uint16</td>
</tr>
<tr>
<td>44</td>
<td>2</td>
<td>Maximum UDF Write Revision</td>
<td>Uint16</td>
</tr>
<tr>
<td>46</td>
<td>??</td>
<td>Implementation Use</td>
<td>byte</td>
</tr>
</tbody>
</table>
```
Implementation ID - The implementation identifier EntityID of the implementation which last modified anything within the scope of this EntityID. The scope of this EntityID is the Logical Volume Descriptor, and the contents of the associated Logical Volume. This field allows an implementation to identify which implementation last modified the contents of a Logical Volume.

Number of Files - The current number of files in the associated Logical Volume. This information is needed by the Macintosh OS. All implementations shall maintain this information. NOTE: This value does not include Extended Attributes or streams as part of the file count.

Number of Directories - The current number of directories in the associated Logical Volume. This information is needed by the Macintosh OS. All implementations shall maintain this information. NOTE: The root directory shall be included in the directory count. The directory count does not include stream directories.

Minimum UDF Read Revision - Shall indicate the minimum recommended revision of the UDF specification that an implementation is required to support to successfully be able to read all potential structures on the media. This number shall be stored in binary coded decimal format, for example #0150 would indicate revision 1.50 of the UDF specification.

Minimum UDF Write Revision - Shall indicate the minimum revision of the UDF specification that an implementation is required to support to successfully be able to modify all structures on the media. This number shall be stored in binary coded decimal format, for example #0150 would indicate revision 1.50 of the UDF specification.

Maximum UDF Write Revision - Shall indicate the maximum revision of the UDF specification that an implementation that has modified the media has supported. An implementation shall update this field only if it has modified the media and the level of the UDF specification it supports is higher than the current value of this field. This number shall be stored in binary coded decimal format, for example #0150 would indicate revision 1.50 of the UDF specification.

Implementation Use - Contains implementation specific information unique to the implementation identified by the Implementation ID.
2.2.7 Implementation Use Volume Descriptor

```c
struct ImpUseVolumeDescriptor { /* ECMA 167 3/10.4 */
    struct tag DescriptorTag;
    Uint32 VolumeDescriptorSequenceNumber;
    struct EntityID ImplementationIdentifier;
    byte ImplementationUse[460];
}
```

This section defines an UDF Implementation Use Volume Descriptor. This descriptor shall be recorded on every Volume of a Volume Set. The Volume may also contain additional Implementation Use Volume Descriptors that are implementation specific. The intended purpose of this descriptor is to aid in the identification of a Volume within a Volume Set that belongs to a specific Logical Volume.

NOTE: An implementation may still record an additional Implementation Use Volume Descriptor in its own format on the media. The UDF Implementation Use Volume Descriptor does not preclude an additional descriptor.

2.2.7.1 EntityID ImplementationIdentifier

The Identifier field of this EntityID shall specify "*UDF LV Info". Refer to section 2.1.5 on Entity Identifier.

2.2.7.2 bytes ImplementationUse

The implementation use area shall contain the following structure:

```c
struct LVInformation {
    struct charspec LVICharset,
    dstring LogicalVolumeIdentifier[128],
    dstring LVInfo1[36],
    dstring LVInfo2[36],
    dstring LVInfo3[36],
    struct EntityID ImplementationID,
    bytes ImplementationUse[128];
}
```

2.2.7.2.1 charspec LVICharset

Interpreted as specifying the character sets allowed in the LogicalVolumeIdentifier and LVInfo fields.

Shall be set to indicate support for CS0 only as defined in 2.1.2.
2.2.7.2.2  **dstring LogicalVolumeIdentifier**
Identifies the Logical Volume referenced by this descriptor.

2.2.7.2.3  **dstring LVInfo1, LVInfo2 and LVInfo3**
The fields LVInfo1, LVInfo2 and LVInfo3 should contain additional information to aid in the identification of the media. For example the LVInfo fields could contain information such as *Owner Name*, *Organization Name*, and *Contact Information*.

2.2.7.2.4  **struct EntityID ImplementationID**
Refer to section 2.1.5 on Entity Identifier.

2.2.7.2.5  **bytes ImplementationUse[128]**
This area may be used by the implementation to store any additional implementation specific information.
2.2.8 Virtual Partition Map

This is an extension of ECMA 167 to expand its scope to include sequentially written media (eg. CD-R). This extension is for a partition map entry to describe a virtual space.

The Logical Volume Descriptor contains a list of partitions that make up a given volume. As the virtual partition cannot be described in the same manner as a physical partition, a Type 2 partition map defined below shall be used.

If a Virtual Partition Map is recorded, then the Logical Volume Descriptor shall contain at least two partition maps. One partition map shall be recorded as a Type 1 partition map. One partition map shall be recorded as a Type 2 partition map. The format of this Type 2 partition map shall be as specified in the following table.

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Partition Map Type</td>
<td>Uint8 = 2</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Partition Map Length</td>
<td>Uint8 = 64</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>Reserved</td>
<td>#00 bytes</td>
</tr>
<tr>
<td>4</td>
<td>32</td>
<td>Partition Type Identifier</td>
<td>EntityID</td>
</tr>
<tr>
<td>36</td>
<td>2</td>
<td>Volume Sequence Number</td>
<td>Uint16</td>
</tr>
<tr>
<td>38</td>
<td>2</td>
<td>Partition Number</td>
<td>Uint16</td>
</tr>
<tr>
<td>40</td>
<td>24</td>
<td>Reserved</td>
<td>#00 bytes</td>
</tr>
</tbody>
</table>

- Partition Type Identifier:
  - Flags = 0
  - Identifier = *UDF Virtual Partition
  - IdentifierSuffix is recorded as in section 2.1.5.3
- Volume Sequence Number = volume upon which the VAT and Partition is recorded
- Partition Number = the partition number in the Type 1 partition map in the same logical volume descriptor.

2.2.9 Sparable Partition Map

Certain disk/drive systems do not perform defect management (eg. CD-RW). To provide an apparent defect-free space for these systems, a partition of type 2 is used. The partition map defines the partition number, packet size (see section 1.3.2), and size and locations of the sparing tables. This type 2 map is intended to replace the type 1 map normally found on the media. There should not be a type 1 map recorded if a Sparable Partition Map is recorded. The Sparable Partition Map identifies not only the partition number and the volume sequence.
number, but also identifies the packet length and the sparing tables. A Sparable Partition Map shall not be recorded on disk/drive systems that perform defect management.

### Layout of Type 2 partition map for sparable partition

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>

</tr>
<tr>
<td>48 + 4 * N_ST</td>
<td>Pad</td>
<td>#00 bytes</td>
<td></td>
</tr>
</tbody>
</table>

- Partition Type Identifier:
  - Flags = 0
  - Identifier = *UDF Sparable Partition
  - IdentifierSuffix is recorded as in section 2.1.5.3.
- Partition Number = the number of this partition. Shall identify a Partition Descriptor associated with this partition.
- Packet Length = the number of user data blocks per fixed packet. This value is specified in the medium specific section of Appendix 6.
- Number of Sparing Tables = the number of redundant tables recorded. This shall be a value in the range of 1 to 4.
- Size of each sparing table = Length, in bytes, allocated for each sparing table.
- Locations of sparing tables = the start locations of each sparing table specified as a media block address. Implementations should align the start of each sparing table with the beginning of a packet. Implementations should record at least two sparing tables in physically distant locations.

#### 2.2.10 Virtual Allocation Table

The Virtual Allocation Table (VAT) is used on sequentially written media (e.g., CD-R) to give the appearance of randomly writable media to the system. The existence of this partition is identified in the partition maps. The VAT shall only be recorded on sequentially written media (e.g., CD-R).

The VAT is a map that translates Virtual Addresses to logical addresses. It shall be recorded as a file identified by a File Entry ICB (VAT ICB) that allows great flexibility in building the table. The VAT ICB is the last sector recorded in any transaction. The VAT itself may be recorded at any location.
The VAT shall be identified by a File Entry ICB with a file type of 248. This ICB shall be the last valid data sector recorded. Error recovery schemes can find the last valid VAT by finding ICBs with file type 248.

This file, when small, can be embedded in the ICB that describes it. If it is larger, it can be recorded in a sector or sectors preceding the ICB. The sectors do not have to be contiguous, which allows writing only new parts of the table if desired. This allows small incremental updates, even on disks with many directories.

When the VAT is small (a small number of directories on the disk), the VAT is updated by writing a new file ICB with the VAT embedded. When the VAT becomes too large to fit in the ICB, writing a single sector with the VAT and a second sector with the ICB is required. Beyond this point, more than one sector is required for the VAT. However, as multiple extents are supported, updating the VAT may consist of writing only the sector or sectors that need updating and writing the ICB with pointers to all of the pieces of the VAT.

The Virtual Allocation Table is used to redirect requests for certain information to the proper logical location. The indirection provided by this table provides the appearance of direct overwrite capability. For example, the ICB describing the root directory could be referenced as virtual sector 1. A virtual sector is contained in a partition identified by a virtual partition map entry. Over the course of updating the disk, the root directory may change. When it changes, a new sector describing the root directory is written, and its Logical Block Address is recorded as the Logical Block Address corresponding to virtual sector 1. Nothing that references virtual sector 1 needs to change, as it still points to the most current virtual sector 1 that exists, even though it exists at a new Logical Block Address.

The use of virtual addressing allows any desired structure to become effectively rewritable. The structure is rewritable when every pointer that references it does so only by its Virtual Address. When a replacement structure is written, the virtual reference does not need to change. The proper entry in the VAT is changed to reflect the new Logical Block Address of the corresponding Virtual Address and all virtual references then indirectly point to the new structure. All structures that require updating, such as directory ICBs, shall be referenced by a Virtual Address. As each structure is updated, its corresponding entry in the VAT ICB shall be updated.

The VAT shall be recorded as a sequence of Uint32 entries in a file. Each entry shall be the offset, in sectors, into the physical partition in which the VAT is located. The first entry shall be for the virtual partition sector 0, the second entry for virtual partition sector 1, etc. The Uint32 entries shall follow the VAT header. The entry for the previous VAT ICB allows for viewing the file system as it appeared in an earlier state. If this field is #FFFFFFFF, then no such ICB is specified.
Virtual Allocation Table structure

<table>
<thead>
<tr>
<th>Offset</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>Length of Header (=L_HD)</td>
<td>Uint16</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>Length of Implementation Use (=L_IU)</td>
<td>Uint16</td>
</tr>
<tr>
<td>4</td>
<td>128</td>
<td>Logical Volume Identifier</td>
<td>dstring</td>
</tr>
<tr>
<td>132</td>
<td>4</td>
<td>Previous VAT ICB location</td>
<td>Uint32</td>
</tr>
<tr>
<td>136</td>
<td>4</td>
<td>Number of Files</td>
<td>Uint32</td>
</tr>
<tr>
<td>140</td>
<td>4</td>
<td>Number of Directories</td>
<td>Uint32</td>
</tr>
<tr>
<td>144</td>
<td>2</td>
<td>Minimum UDF Read Version</td>
<td>Uint16</td>
</tr>
<tr>
<td>146</td>
<td>2</td>
<td>Minimum UDF Write Version</td>
<td>Uint16</td>
</tr>
<tr>
<td>148</td>
<td>2</td>
<td>Maximum UDF Write Version</td>
<td>Uint16</td>
</tr>
<tr>
<td>152</td>
<td>L_IU</td>
<td>Implementation Use</td>
<td>bytes</td>
</tr>
<tr>
<td>152 + L_IU</td>
<td>4</td>
<td>VAT entry 0</td>
<td>Uint32</td>
</tr>
<tr>
<td>156 + L_IU</td>
<td>4</td>
<td>VAT entry 1</td>
<td>Uint32</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Information Length - 4</td>
<td>4</td>
<td>VAT entry n</td>
<td>Uint32</td>
</tr>
</tbody>
</table>

Length of Header - Indicates the amount of data preceding the VAT entries. This value shall be 152 + L_IU.

Length of Implementation Use - Shall specify the number of bytes in the Implementation Use field. If this field is non-zero, the value shall be at least 32 and be an integral multiple of 4.

Logical Volume Identifier - Shall identify the logical volume. This field shall be used by implementations instead of the corresponding field in the Logical Volume Descriptor. The value of this field should be the same as the field in the LVD until changed by the user.

Previous VAT ICB Location - Shall specify the logical block number of an earlier VAT ICB in the partition identified by the partition map entry. If this field is #FFFFFFFF, no such ICB is specified.

Number of Files – The current number of files in the associated Logical Volume. This information is needed by the Macintosh OS. All implementations shall maintain this information. The contents of this field shall be used by implementations instead of the corresponding field in the LVID.

NOTE: This value does not include Extended Attributes or streams as part of the file count.
**Number of Directories** - The current number of directories in the associated Logical Volume. This information is needed by the Macintosh OS. All implementations shall maintain this information. The contents of this field shall be used by implementations instead of the corresponding field in the LVID.

**NOTE:** The root directory shall be included in the directory count. The directory count does not include stream directories.

**Minimum UDF Read Version** - Defined in 2.2.6. The contents of this field shall be used by implementations instead of the corresponding field in the Logical Volume Integrity Descriptor (LVID).

**Minimum UDF Write Version** - Defined in 2.2.6. The contents of this field shall be used by implementations instead of the corresponding field in the LVID.

**Maximum UDF Write Version** - Defined in 2.2.6. The contents of this field shall be used by implementations instead of the corresponding field in the LVID.

**Implementation Use** - If non-zero in length, shall begin with an EntityID identifying the usage of the remainder of the Implementation Use area.

**VAT Entry** - VAT entry \( n \) shall identify the logical block number of the virtual block \( n \). An entry of \#FFFFFFFF indicates that the virtual sector is currently unused. The LBN specified is located in the partition identified by the partition map entry. The number of entries in the table can be determined from the VAT file size in the ICB:

\[
\text{Number of entries (N)} = \frac{(\text{Information Length} - \text{L_HD})}{4}.
\]

### 2.2.11 Sparing Table

Certain disk/drive systems do not perform defect management (eg. CD-RW). A Sparing Table is used to provide an apparent defect-free space for these systems. Certain media can only be written in groups of sectors (“packets”), further complicating relocation: a whole packet must be relocated rather than only the sectors being written. To address this issue a sparable partition is identified in the partition map, which further identifies the location of the sparing tables. The sparing table identifies relocated areas on the media. Sparing tables are identified by a sparable partition map. Sparing tables shall not be recorded on disk/drive systems that perform defect management.

Sparing Tables point to space allocated for sparing and contains a list of mappings of defective sectors to their replacements. Separate copies of the sparing tables shall be recorded in separate packets. All instances of the sparing table shall be kept up to date.
Partitions map logical space to physical space. Normally, this is a linear mapping where an offset and a length are specified. A sparable partition is based on this mapping, where the offset and length of a partition within physical space is specified by a Partition Descriptor (see 2.2.12). A sparable partition shall begin and end on a packet boundary. The sparing table further specifies an exception list of logical to physical mappings. All mappings are one packet in length. The packet size is specified in the sparable partition map.

Available sparing areas may be anywhere on the media, either inside or outside of a partition. If located inside a partition, sparable space shall be marked as allocated and shall be included in the Non-Allocatable Space Stream. The mapped locations should be filled in at format time; the original locations are assigned dynamically as errors occur. Each sparing table shall be structured as shown below.

<table>
<thead>
<tr>
<th>BP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>16</td>
<td>Descriptor Tag</td>
<td>tag = 0</td>
</tr>
<tr>
<td>16</td>
<td>32</td>
<td>Sparing Identifier</td>
<td>EntityID</td>
</tr>
<tr>
<td>48</td>
<td>2</td>
<td>Reallocation Table Length (=RT_L)</td>
<td>Uint16</td>
</tr>
<tr>
<td>50</td>
<td>2</td>
<td>Reserved</td>
<td>#00 bytes</td>
</tr>
<tr>
<td>52</td>
<td>4</td>
<td>Sequence Number</td>
<td>Uint32</td>
</tr>
<tr>
<td>56</td>
<td>8*RT_L</td>
<td>Map Entry</td>
<td>Map Entries</td>
</tr>
</tbody>
</table>

This structure may be larger than a single sector if necessary.

- **Descriptor Tag**
  - Contains a Tag Identifier of 0, which indicates that the format of the Descriptor Tag is not specified by ECMA 167. All other fields of the Descriptor Tag shall be valid, as if the Tag Identifier were one of the values defined by ECMA 167.

- **Sparing Identifier**
  - Flags = 0
  - Identifier = *UDF Sparing Table
  - IdentifierSuffix is recorded as in UDF 2.1.5.3

- **Reallocation Table Length**
  - Indicates the number of entries in the Map Entry table.

- **Sequence Number**
  - Contains a number that shall be incremented each time the sparing table is updated.

- **Map Entry**
  - A map entry is described in the table below. Maps shall be sorted in ascending order by the Original Location field.
### Map Entry description

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>Original Location</td>
<td>Uint32</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Mapped Location</td>
<td>Uint32</td>
</tr>
</tbody>
</table>

- **Original Location**
  Logical Block Address of the packet to be spared. The address of a packet is the address of the first user data block of a packet. If this field is `#FFFFFFFF`, then this entry is available for sparing. If this field is `#FFFFFFF0`, then the corresponding mapped location is marked as defective and should not be used for mapping. Original Locations of `#FFFFFFF1` through `#FFFFFFFFE` are reserved.

- **Mapped Location**
  Physical Block Address of active data. Requests to the original packet location are redirected to the packet location identified here. All Mapped Location entries shall be valid, including those entries for which the Original Location is `#FFFFFFF0`, `#FFFFFFFF`, or reserved. If the mapped location overlaps a partition, that partition shall have that space marked as allocated and that space shall be part of the Non-Allocatable Space Stream.

### 2.2.12 Partition Descriptor

```c
struct PartitionDescriptor {
  /* ECMA 167 3/10.5 */
  struct tag DescritorTag;
  Uint32 VolumeDescriptorSequenceNumber;
  Uint16 PartitionFlags;
  Uint16 PartitionNumber;
  struct EntityID PartitionContents;
  byte PartitionContentsUse[128];
  Uint32 AccessType;
  Uint32 PartitionStartingLocation;
  Uint32 PartitionLength;
  struct EntityID ImplementationIdentifier;
  byte ImplementationUse[128];
  byte Reserved[156];
};
```

#### 2.2.12.1 Struct EntityID PartitionContents

For more information on the proper handling of this field see the section on *Entity Identifier*.

#### 2.2.12.2 Uint32 PartitionStartingLocation

For a Sparable Partition, the value of this field shall be an integral multiple of the Packet Length. The Packet Length is defined in the Sparable Partition Map.
2.2.12.3 **Uint32 PartitionLength**

For a Sparable Partition, the value of this field shall be an integral multiple of the Packet Length. The Packet Length is defined in the Sparable Partition Map.

2.2.12.4 **Struct EntityID ImplementationIdentifier**

For more information on the proper handling of this field see the section on *Entity Identifier*. 
2.3 Part 4 - File System

2.3.1 Descriptor Tag

```
struct tag { /* ECMA 167 4/7.2 */
    Uint16 TagIdentifier;
    Uint16 DescriptorVersion;
    Uint8  TagChecksum;
    byte   Reserved;
    Uint16  TagSerialNumber;
    Uint16  DescriptorCRC;
    Uint16  DescriptorCRCLength;
    Uint32  TagLocation;
}
```

2.3.1.1 Uint16 TagSerialNumber

Ignored. Intended for disaster recovery.

Shall be set to the TagSerialNumber value for the Anchor Volume Descriptor Pointers on this volume.

The same applies as for volume structure TagSerialNumber values, see 2.2.1.1 and 2.1.6.

2.3.1.2 Uint16 DescriptorCRCLength

CRCs shall be supported and calculated for each descriptor, unless otherwise noted.

The value of this field shall be set to: (Size of the Descriptor) - (Length of Descriptor Tag). When reading a descriptor the CRC should be validated.

NOTE: The DescriptorCRCLength field must not be used to determine the actual length of the descriptor or the number of bytes to read. These lengths do not match in all cases; there are exceptions in the standard where the Descriptor CRC Length need not match the length of the descriptor.

2.3.1.3 Uint32 TagLocation

For structures referenced via a virtual address (i.e. referenced through the VAT), this value shall be the virtual address, not the physical or logical address.
2.3.2 File Set Descriptor

struct FileSetDescriptor {
    /* ECMA 167 4/14.1 */
    struct tag DescriptorTag;
    struct timestamp RecordingDateandTime;
    Uint16 InterchangeLevel;
    Uint16 MaximumInterchangeLevel;
    Uint32 CharacterSetList;
    Uint32 MaximumCharacterSetList;
    Uint32 FileSetNumber;
    Uint32 FileSetDescriptorNumber;
    struct charspec LogicalVolumeIdentifierCharacterSet;
    dstring LogicalVolumeIdentifier[128];
    struct charspec FileSetCharacterSet;
    dstring FileSetIdentifier[32];
    dstring CopyrightFileIdentifier[32];
    dstring AbstractFileIdentifier[32];
    struct long_ad RootDirectoryICB;
    struct EntityID DomainIdentifier;
    struct long_ad NextExtent;
    struct long_ad StreamDirectoryICB;
    byte Reserved[32];
}

Only one FileSet descriptor shall be recorded. On WORM media, multiple FileSets may be recorded.

The UDF provision for multiple File Sets is as follows:

- Multiple FileSets are only allowed on WORM media.
- The default FileSet shall be the one with the highest FileSetNumber.
- Only the default FileSet may be flagged as writable. All other FileSets in the sequence shall be flagged HardWriteProtect (see 2.1.5.3).
- No writable FileSet shall reference any metadata structures which are referenced (directly or indirectly) by any other FileSet. Writable FileSets may, however, reference the actual file data extents.

Within a FileSet on WORM, if all files and directories have been recorded with ICB strategy type 4, then the DomainID of the corresponding File Set Descriptor shall be marked as HardWriteProtected.

The intended purpose of multiple FileSets on WORM is to support the ability to have multiple archive images on the media. For example one FileSet could represent a backup of a certain set of information made at a specific point in time. The next FileSet...
could represent another backup of the same set of information made at a later point in time.

2.3.2.1 Uint16 InterchangeLevel

Interpreted as specifying the current interchange level (as specified in ECMA 167 4/15), of the contents of the associated file set and the restrictions implied by the specified level.

Shall be set to a level of 3.

An implementation shall enforce the restrictions associated with the specified current Interchange Level.

2.3.2.2 Uint16 MaximumInterchangeLevel

Interpreted as specifying the maximum interchange level of the contents of the associated file set. This value restricts to what the current Interchange Level field may be set.

Shall be set to level 3.

2.3.2.3 Uint32 CharacterSetList

Interpreted as specifying the character set(s) specified by any field, whose contents are specified to be a charspec, of any descriptor specified in Part 4 of ECMA 167 and recorded in the file set described by this descriptor.

Shall be set to indicate support for CS0 only as defined in 2.1.2.

2.3.2.4 Uint32 MaximumCharacterSetList

Interpreted as specifying the maximum supported character set in the associated file set and the restrictions implied by the specified level.

Shall be set to indicate support for CS0 only as defined in 2.1.2.

2.3.2.5 struct charspec LogicalVolumeIdentifierCharacterSet

Interpreted as specifying the d-characters allowed in the Logical Volume Identifier field.

Shall be set to indicate support for CS0 as defined in 2.1.2.

2.3.2.6 struct charspec FileSetCharacterSet

Interpreted as specifying the d-characters allowed in dstring fields defined in Part 4 of ECMA 167 that are within the scope of the FileSetDescriptor.
2.3.2.7 struct EntityID DomainIdentifier

Interpreted as specifying a domain specifying rules on the use of, and restrictions on, certain fields in the descriptors. If this field is NULL then it is ignored, otherwise the Entity Identifier rules are followed.

This field shall indicate that the scope of this File Set Descriptor conforms to the domain defined in this document, therefore the ImplementationIdentifier shall be set to:

"OSTA UDF Compliant"

As described in the section on Entity Identifier the IdentifierSuffix field of this EntityID shall contain the revision of this document for which the contents of the Logical Volume is compatible. For more information on the proper handling of this field see section 2.1.5.3.

NOTE: The IdentifierSuffix field of this EntityID contains SoftWriteProtect and HardWriteProtect flags.

2.3.3 Partition Header Descriptor

struct PartitionHeaderDescriptor { /* ECMA 167 4/14.3 */
    struct short_ad UnallocatedSpaceTable;
    struct short_ad UnallocatedSpaceBitmap;
    struct short_ad PartitionIntegrityTable;
    struct short_ad FreedSpaceTable;
    struct short_ad FreedSpaceBitmap;
    byte Reserved[88];
}

As a point of clarification the logical blocks represented as Unallocated are blocks that are ready to be written without any preprocessing. In the case of Rewritable media this would be a write without an erase pass. The logical blocks represented as Freed are blocks that are not ready to be written, and require some form of preprocessing. In the case of Rewritable media this would be a write with an erase pass.

NOTE: The use of Space Tables or Space Bitmaps shall be consistent across a Logical Volume. Space Tables and Space Bitmaps shall not both be used at the same time within a Logical Volume.
2.3.3.1 struct short_ad PartitionIntegrityTable
    Shall be set to all zeros since PartitionIntegrityEntries are not used.

2.3.4 File Identifier Descriptor
    struct FileIdentifierDescriptor {
        struct tag DescriptorTag;
        Uint16 FileVersionNumber;
        Uint8 FileCharacteristics;
        Uint8 LengthOfFileIdentifier;
        struct long_ad ICB;
        Uint16 LengthOfImplementationUse;
        byte ImplementationUse[];
        char FileIdentifier[];
        byte Padding[];
    }

    The File Identifier Descriptor shall be restricted to the length of at most one Logical Block.

    NOTE: All UDF directories shall include a File Identifier Descriptor that indicates the location of the parent directory. The File Identifier Descriptor describing the parent directory shall be the first File Identifier Descriptor recorded in the directory. The parent directory of the Root directory shall be Root, as stated in ECMA 167 4/8.6

2.3.4.1 Uint16 FileVersionNumber
    There shall be only one version of a file as specified below with the value being set to 1.

    Shall be set to 1.

2.3.4.2 File Characteristics
    The deleted bit may be used to mark a file or directory as deleted instead of removing the FID from the directory, which requires rewriting the directory from that point to the end. If the space for the file or directory is deallocated, the implementation shall set the ICB field to zero, as all fields in a FID must be valid even if the deleted bit is set. See [4/14.4.3], note 21 and [4/14.4.5].

    ECMA 167 4/8.6 requires that the File Identifiers (and File Version Numbers, which shall always be 1) of all FIDs in a directory shall be unique. While the standard is silent on whether FIDs with the deleted bit set are subject to this requirement, the intent is that they are not. FIDs with the deleted bit set are not subject to the uniqueness requirement, as interpreted by UDF.
In order to assist a UDF implementation that may have read the standard without this interpretation, implementations shall follow these rules when a FID’s deleted bit is set:

If the compression ID of the File Identifier is 8, rewrite the compression ID to 254. If the compression ID of the File Identifier is 16, rewrite the compression ID to 255. Leave the remaining bytes of the File Identifier unchanged.

In this way a utility wishing to undelete a file or directory can recover the original name by reversing the rewrite of the compression ID.

NOTE: Implementations should re-use FIDs that have the deleted bit set to one and ICBs set to zero in order to avoid growing the size of the directory unnecessarily.

2.3.4.3 struct long_ad ICB

The *Implementation Use* bytes of the long_ad in all *File Identifier Descriptors* shall be used to store the UDF Unique ID for the file and directory namespace.

The *Implementation Use* bytes of a long_ad hold an ADImpUse structure as defined by 2.3.10.1. The four impUse bytes of that structure will be interpreted as a Uint32 holding the UDF Unique ID.

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>Flags (see 2.3.10.1)</td>
<td>Uint16</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>UDF Unique ID</td>
<td>Uint32</td>
</tr>
</tbody>
</table>

Section 3.2.1 Logical Volume Header Descriptor describes how *UDF Unique ID* field in Implementation Use bytes of the long_ad in the File Identifier Descriptor and the *UniqueID* field in the File Entry and Extended File Entry are set.

2.3.4.4 Uint16 LengthofImplementationUse

Shall specify the length of the *ImplementationUse* field.

Shall specify the length of the *ImplementationUse* field. This field may contain zero, indicating that the ImplementationUse field has not been used. Otherwise, this field shall contain at least 32 as required by 2.3.4.5.

When writing a File Identifier Descriptor to write-once media, to ensure that the Descriptor Tag field of the next FID will never span a block boundary, if there are less than 16 bytes remaining in the current block after the FID, the length of the FID shall be increased (using the Implementation Use field) enough to prevent this. Remember that in the latter case, the Implementation Use field shall be at least 32 bytes.
2.3.4.5 byte ImplementationUse

If the LengthofImplementationUse field is non ZERO then the first 32 bytes of this field shall be interpreted as specifying the implementation identifier EntityID of the implementation which last modified the File Identifier Descriptor.

If the LengthofImplementationUse field is non ZERO then the first 32 bytes of this field shall be set to the implementation identifier EntityID of the current implementation.

NOTE: For additional information on the proper handling of this field refer to the section on Entity Identifier.

This field allows an implementation to identify which implementation last created and/or modified a specific File Identifier Descriptor.

2.3.5 ICB Tag

struct icbtag { /* ECMA 167 4/14.6 */
    Uint32 PriorRecordedNumberofDirectEntries;
    Uint16 StrategyType;
    byte StrategyParameter[2];
    Uint16 NumberOfEntries;
    byte Reserved;
    Uint8 FileType;
    Lb_addr ParentICBLocation;
    Uint16 Flags;
}

2.3.5.1 Uint16 StrategyType

The content of this field specifies the ICB strategy type used. For the purposes of read access an implementation shall support strategy types 4 and 4096.

Shall be set to 4 or 4096.

NOTE: Strategy type 4096, which is defined in the appendix, is intended for primary use on WORM media, but may also be used on rewritable and overwritable media.

2.3.5.2 Uint8 FileType

As a point to clarification a value of 5 shall be used for a standard byte addressable file, not 0. The value of 248 shall be used for the VAT (refer to 2.2.10). The value of 249
shall be used to indicate a Real-Time file (see Appendix 6.11). Values of 250 to 255 shall not be used.

2.3.5.2.1 File Type 249
Files with FileType 249 require special commands to access the data space of this file. To avoid possible damage, if an implementation does not support these commands it shall not issue any command that would access or modify the data space of this file. This includes but is not limited to reading, writing and deleting the file.

2.3.5.3 ParentICBLocation
The use of this field is optional.

NOTE: In ECMA 167-4/14.6.7 it states, “If this field contains 0, then no such ICB is specified.” This is a flaw in the ECMA standard in that an implementation could store an ICB at logical block address 0. Therefore, if you decide to use this field, do not store an ICB at logical block address 0.

2.3.5.4 Uint16 Flags
Bits 0-2: These bits specify the type of allocation descriptors used. Refer to the section on Allocation Descriptors for the guidelines on choosing which type of allocation descriptor to use.

Bit 3 (Sorted):
.sessions For OSTA UDF compliant media this bit shall indicate (ZERO) that directories may be unsorted.

&bull; Shall be set to ZERO.

Bit 4 (Non-relocatable):
.sessions For OSTA UDF compliant media this bit shall indicate (ONE) if the file is non-relocatable. If ONE, an implementation shall set the bit to ZERO if a modification will contravene the definition of this bit in ECMA 167-4/14.6.8.

&bull; Should be set to ZERO unless required.

NOTE: This flag is not a lock on the file in any way. It is used to indicate that an implementation has arranged the allocation of the file to satisfy specific application requirements. In these cases, any remapping of a written block (see UDF sparable partitions) or defragmentation of the file might not be desired. If a file with this flag set to ONE is copied, then the new copy of the file should have this bit set to ZERO.

Bit 9 (Contiguous):
For OSTA UDF compliant media this bit may indicate (ONE) that the file is contiguous. An implementation may reset this bit to ZERO to indicate that the file may be non-contiguous if the implementation can not assure that the file is contiguous.

Should be set to ZERO.

**Bit 11 (Transformed):**

For OSTA UDF compliant media this bit shall indicate (ZERO) that no transformation has taken place.

Shall be set to ZERO.

The methods used for data compression and other forms of data transformation might be addressed in a future OSTA document.

**Bit 12 (Multi-versions):**

For OSTA UDF compliant media this bit shall indicate (ZERO) that multi-versioned files are not present.

Shall be set to ZERO.
2.3.6 File Entry

```c
struct FileEntry {
    /* ECMA 167 4/14.9 */
    struct tag DescriptorTag;
    struct icbtag ICBTag;
    Uint32 Uid;
    Uint32 Gid;
    Uint32 Permissions;
    Uint16 FileLinkCount;
    Uint8 RecordFormat;
    Uint8 RecordDisplayAttributes;
    Uint32 RecordLength;
    Uint64 InformationLength;
    Uint64 LogicalBlocksRecorded;
    struct timestamp AccessTime;
    struct timestamp ModificationTime;
    struct timestamp AttributeTime;
    Uint32 Checkpoint;
    struct long_ad ExtendedAttributeICB;
    struct EntityID ImplementationIdentifier;
    Uint64 UniqueID;
    Uint32 LengthofExtendedAttributes;
    Uint32 LengthofAllocationDescriptors;
    byte ExtendedAttributes[];
    byte AllocationDescriptors[];
}
```

NOTE: The total length of a FileEntry shall not exceed the size of one logical block.

2.3.6.1 Uint8 RecordFormat;

✈ For OSTA UDF compliant media a value of zero shall indicate that the structure of the information recorded in the file is not specified by this field.

✈ Shall be set to ZERO.

2.3.6.2 Uint8 RecordDisplayAttributes;

✈ For OSTA UDF compliant media a value of zero shall indicate that the structure of the information recorded in the file is not specified by this field.

✈ Shall be set to ZERO.
2.3.6.3 Uint32 RecordLength;
    ☀ For OSTA UDF compliant media a value of zero shall indicate that the structure of
    the information recorded in the file is not specified by this field.
    ☀ Shall be set to ZERO.

2.3.6.4 Uint64 InformationLength
    In most cases, the InformationLength can be reconstructed during a recovery operation by
    finding the sum of the lengths of each of the allocation descriptors. However, space may be
    allocated after the end of the file (identified as a “file tail.”). As “unrecorded and allocated”
    space is a legal part of a file body, using the allocation descriptors to determine the
    information length is possible under the following conditions:

    - if an allocation descriptor exists with an extent length that is not a multiple of the block
      size.
    - if no such extent exists and the extent type of the last allocation descriptor with an extent
      length unequal to 0 is not equal to “unrecorded and allocated”.

    Only the last extent of the file body may have an extent length that is not a multiple of the

2.3.6.5 Uint64 LogicalBlocksRecorded
    For files and directories with embedded data the value of this field shall be ZERO.

2.3.6.6 struct EntityID ImplementationIdentifier;
    Refer to the section on Entity Identifier.

2.3.6.7 Uint64 UniqueID
    For the root directory of a file set this value shall be set to ZERO.

    Section 3.2.1 Logical Volume Header Descriptor describes how the UDF Unique ID
    field in the Implementation Use bytes of the long_ad in the File Identifier Descriptor and
    the UniqueID file in the File Entry and Extended File Entry are set.
2.3.7 Unallocated Space Entry

```c
struct UnallocatedSpaceEntry {
    struct tag DescriptorTag;
    struct icbtag ICBTag;
    Uint32 LengthOfAllocationDescriptors;
    byte AllocationDescriptors[];
}
```

**NOTE:** The maximum length of an UnallocatedSpaceEntry shall be one Logical Block.

### 2.3.7.1 byte AllocationDescriptors

Only Short Allocation Descriptors shall be used.

**NOTE:** The upper 2 bits of the extent length field in allocation descriptors specify an extent type (ECMA 167 4/14.14.1.1). For the allocation descriptors specified for the UnallocatedSpaceEntry the type shall be set to a value of 1 to indicate *extent allocated but not recorded*, or shall be set to a value of 3 to indicate *the extent is the next extent of allocation descriptors*. This next extent of allocation descriptors shall be limited to the length of one Logical Block.

*AllocationDescriptors* shall be ordered sequentially in ascending location order. No overlapping *AllocationDescriptors* shall exist in the table. For example, ad.location = 2, ad.length = 2048 (logical block size = 1024) then nextad.location = 3 is not allowed. Adjacent *AllocationDescriptors* shall not be contiguous. For example ad.location = 2, ad.length = 1024 (logical block size = 1024), nextad.location = 3 is not allowed and would instead be a single *AllocationDescriptor*, ad.location = 2, ad.length = 2048. The only case where adjacent *AllocationDescriptors* may be contiguous is when the ad.length of one of the adjacent *AllocationDescriptors* is equal to the maximum *AllocationDescriptors* length.
2.3.8 Space Bitmap Descriptor

```
struct SpaceBitmap { /* ECMA 167 4/14.12 */
  struct Tag     DescriptorTag;
  Uint32        NumberOfBits;
  Uint32        NumberOfBytes;
  byte          Bitmap[];
}
```

2.3.8.1 struct Tag DescriptorTag

The calculation and maintenance of the DescriptorCRC field of the Descriptor Tag for the SpaceBitmap descriptor is optional. If the CRC is not maintained then both the DescriptorCRC and DescriptorCRCLength fields shall be ZERO.

2.3.9 Partition Integrity Entry

```
struct PartitionIntegrityEntry { /* ECMA 167 4/14.13 */
  struct tag     DescriptorTag;
  struct icbtag  ICBTag;
  struct timestamp RecordingTime;
  Uint8          IntegrityType;
  byte           Reserved[175];
  struct EntityID ImplementationIdentifier;
  byte           ImplementationUse[256];
}
```

With the functionality of the Logical Volume Integrity Descriptor this descriptor is not needed, therefore this descriptor shall not be recorded.

2.3.10 Allocation Descriptors

When constructing the data area of a file an implementation has several types of allocation descriptors from which to choose. The following guidelines shall be followed in choosing the proper allocation descriptor to be used:

*Short Allocation Descriptor* - For a Logical Volume that resides on a single Volume with no intent to expand the Logical Volume beyond the single volume *Short Allocation Descriptors* should be used. For example a Logical Volume created for a standalone drive.

**NOTE:** Refer to section 2.2.2.2 on the MaximumInterchangeLevel.

*Long Allocation Descriptor* - For a Logical Volume that resides on a single Logical Volume with intent to later expand the Logical Volume beyond the single volume, or a
Logical Volume that resides on multiple Volumes *Long Allocation Descriptors* should be used. For example a Logical Volume created for a jukebox.

**NOTE:** There is a benefit of using Long Allocation Descriptors even on a single volume, which is the support of tracking erased extents on rewritable media. See section 2.3.10.1 for additional information.

For both Short and Long Allocation Descriptors, if the 30 least significant bits of the *ExtentLength* field is 0, then the 2 most significant bits shall be 0.

Allocation Descriptors identifying virtual space shall have an extent length of the block size or less. Allocation descriptors identifying file data, directories, or stream data shall identify physical space. ICBs recorded in virtual space shall use long_ad allocation descriptors to identify physical space. The use of short_ad allocation descriptors would identify file data in virtual space if the ICB were in virtual space.

Descriptors recorded in virtual space shall have the virtual logical block number recorded in the Tag Location field.

### 2.3.10.1 Long Allocation Descriptor

```c
struct long_ad { /* ECMA 167 4/14.14.2 */
    Uint32 ExtentLength;
    Lb_addr ExtentLocation;
    byte ImplementationUse[6];
}
```

To allow use of the *ImplementationUse* field by UDF and also by implementations the following structure shall be recorded within the 6-byte *Implementation Use* field.

```c
struct ADImpUse
{
    Uint16 flags;
    byte impUse[4];
}
/*
 * ADImpUse Flags (NOTE: bits 1-15 reserved for future use by UDF)
 */
#define EXTENTErasred (0x01)
```

In the interests of efficiency on *Rewritable* media that benefits from preprocessing, the EXTENTErasred flag shall be set to ONE to indicate an *erased* extent. This applies only to extents of type *not recorded but allocated*. 
### 2.3.11 Allocation Extent Descriptor

```c
struct AllocationExtentDescriptor {
    struct tag DescriptorTag;
    Uint32 PreviousAllocationExtentLocation;
    Uint32 LengthOfAllocationDescriptors;
}
```

The Allocation Extent Descriptor does not contain the Allocation Descriptors itself. UDF will interpret ECMA 167, 4/14.5 in such a way that the Allocation Descriptors will start on the first byte following the `LengthOfAllocationDescriptors` field of the Allocation Extent Descriptor. The Allocation Extent Descriptor together with its Allocation Descriptors constitutes an extent of allocation descriptors. The length of an extent of allocation descriptors shall not exceed the logical block size. Unused bytes following the Allocation Descriptors till the end of the logical block shall have a value of #00.

#### 2.3.11.1 Struct tag DescriptorTag

The `DescriptorTag` should include the Allocation Descriptors following the Allocation Extent Descriptor. The `DescriptorTag` should be either 8 or 8 + `LengthOfAllocationDescriptors`.

#### 2.3.11.2 Uint32 PreviousAllocationExtentLocation

- The previous allocation extent location shall not be used.
- Shall be set to 0.
2.3.12 Pathname

2.3.12.1 Path Component

```c
struct PathComponent { /* ECMA 167 4/14.16.1 */
    Uint8    ComponentType;
    Uint8    LengthOfComponentIdentifier;
    Uint16   ComponentFileVersionNumber;
    char     ComponentIdentifier[ ];
};
```

2.3.12.1.1 Uint16 ComponentFileVersionNumber

There shall be only one version of a file as specified below with the value being set to ZERO.

Shall be set to ZERO.

2.4 Part 5 - Record Structure

Record structure files shall not be created. If they are encountered on the media and they are not supported by the implementation they shall be treated as an uninterpreted stream of bytes.
3. System Dependent Requirements

3.1 Part 1 - General

3.1.1 Timestamp

```c
struct timestamp { /* ECMA 167 1/7.3 */
    Uint16    TypeAndTimezone;
    Uint16    Year;
    Uint8     Month;
    Uint8     Day;
    Uint8     Hour;
    Uint8     Minute;
    Uint8     Second;
    Uint8     Centiseconds;
    Uint8     HundredsofMicroseconds;
    Uint8     Microseconds;
}
```

3.1.1.1 Uint8 Centiseconds;

⚠️ For operating systems that do not support the concept of `centiseconds` the implementation shall ignore this field.

⚠️ For operating systems that do not support the concept of `centiseconds` the implementation shall set this field to ZERO.

3.1.1.2 Uint8 HundredsofMicroseconds;

⚠️ For operating systems that do not support the concept of `hundreds of Microseconds` the implementation shall ignore this field.

⚠️ For operating systems that do not support the concept of a `hundreds of Microseconds` the implementation shall set this field to ZERO.

3.1.1.3 Uint8 Microseconds;

⚠️ For operating systems that do not support the concept of `microseconds` the implementation shall ignore this field.

⚠️ For operating systems that do not support the concept of `microseconds` the implementation shall set this field to ZERO.
3.2 Part 3 - Volume Structure

3.2.1 Logical Volume Header Descriptor

```c
struct LogicalVolumeHeaderDesc { /* ECMA 167 4/14.15 */
    Uint64   UniqueID,
    bytes   reserved[24]
}
```

3.2.1.1 Uint64 UniqueID

This field contains the next *UniqueID* value that should be used. The field is initialized to 16, and it monotonically increases with each assignment described below. Whenever the lower 32-bits of this value reach #FFFFFFFF, the upper 32-bits are incremented by 1, as would be expected for a 64-bit value, but the lower 32-bits “wrap” to 16 (the initialization value). This behavior supports Mac™ OS which uses an ID number space of 16 through $2^{31}$ - 1 inclusive, and will not cause problems for other platforms.

UniqueID is used whenever a new file or directory is created, or another name is linked to an existing file or directory. The File Identifier Descriptors and File Entries/Extended File Entries used for a stream directory and named streams associated with a file or directory do not use UniqueID; rather, the unique ID fields in these structures take their value from the UniqueID of the File Entry/Extended File Entry of the file/directory they are associated with. The same counts for File Entries/Extended File Entries used to define an Extended Attributes Space.

When a file or directory is created, this UniqueID is assigned to the UniqueID field of the File Entry/Extended File Entry, the lower 32-bits of UniqueID are assigned to UDFUniqueID in the Implementation Use bytes of the ICB field in the File Identifier Descriptor (see 2.3.4.3), and UniqueID is incremented by the policy described above.

When a name is linked to an existing file or directory, the lower 32-bits of NextUniqueID are assigned to UDFUniqueID in the Implementation Use bytes of the ICB field in the File Identifier Descriptor (see 2.3.4.3), and UniqueID is incremented by the policy described above.

The lower 32-bits shall be the same in the File Entry/Extended File Entry and its first File Identifier Descriptor, but they shall differ in subsequent FIDs.

All UDF implementations shall maintain the UDFUniqueID in the FID and UniqueID in the FE/EFE as described in this section. The LVHD in a closed Logical Volume Integrity Descriptor shall have a valid UniqueID.
3.3 Part 4 - File System

3.3.1 File Identifier Descriptor

struct FileIdentifierDescriptor {
    struct tag DescriptorTag;
    Uint16 FileVersionNumber;
    Uint8 FileCharacteristics;
    Uint8 LengthOfFileIdentifier;
    struct long_ad ICB;
    Uint16 LengthOfImplementationUse;
    byte ImplementationUse[];
    char FileIdentifier[];
    byte Padding[];
} /* ECMA 167 4/14.4 */

3.3.1.1 Uint8 FileCharacteristics

The following sections describe the usage of the FileCharacteristics under various operating systems.

3.3.1.1.1 MS-DOS, OS/2, Windows 95, Windows NT, Macintosh

- If Bit 0 is set to ONE, the file shall be considered a "hidden" file.
- If Bit 1 is set to ONE, the file shall be considered a "directory."
- If Bit 2 is set to ONE, the file shall be considered "deleted."
- If Bit 3 is set to ONE, the ICB field within the associated FileIdentifier structure shall be considered as identifying the "parent" directory of the directory that this descriptor is recorded in

- If the file is designated as a "hidden" file, Bit 0 shall be set to ONE.
- If the file is designated as a "directory," Bit 1 shall be set to ONE.
- If the file is designated as "deleted," Bit 2 shall be set to ONE.

3.3.1.1.2 UNIX and OS/400

Under UNIX and OS/400 these bits shall be processed the same as specified in 3.3.1.1.1., except for hidden files which will be processed as normal non-hidden files.
3.3.2 ICB Tag

```c
struct icbtag {
    /* ECMA 167 4/14.6 */
    Uint32 PriorRecordedNumberOfDirectEntries;
    Uint16 StrategyType;
    byte StrategyParameter[2];
    Uint16 NumberOfEntries;
    byte Reserved;
    Uint8 FileType;
    Lb_addr ParentICBLocation;
    Uint16 Flags;
}
```

3.3.2.1 Uint16 Flags

3.3.2.1.1 MS-DOS, OS/2, Windows 95, Windows NT

**Bits 6 & 7 (Setuid & Setgid):**

Ignore.

In the interests of maintaining security under environments which do support these bits; bits 6 and 7 shall be set to ZERO if any one of the following conditions are true:

- A file is created.
- The attributes/permissions associated with a file, are modified.
- A file is written to (the contents of the data associated with a file are modified).
- An Extended Attribute associated with the file is modified.
- A stream associated with a file is modified.

**Bit 8 (Sticky):**

Ignore.

Shall be set to ZERO.

**Bit 10 (System):**

Mapped to the MS-DOS / OS/2 system bit.
Mapped from the MS-DOS / OS/2 system bit.

3.3.2.1.2 Macintosh

Bits 6 & 7 (Setuid & Setgid):

Ignored.

In the interests of maintaining security under environments, which do support these bits; bits 6 and 7 shall be set to ZERO if any one of the following conditions are true:

- A file is created.
- The attributes/permissions associated with a file, are modified.
- A file is written to (the contents of the data associated with a file are modified).
- An Extended Attribute associated with the file is modified.
- A stream associated with a file is modified.

Bit 8 (Sticky):

Ignored.

Shall be set to ZERO.

Bit 10 (System):

Ignored.

Shall be set to ZERO.

3.3.2.1.3 UNIX

Bits 6, 7 & 8 (Setuid, Setgid, Sticky):

These bits are mapped to/from the corresponding standard UNIX file system bits.

Bit 10 (System):

Ignored.

Shall be set to ZERO upon file creation only, otherwise maintained.
3.3.2.1.4 OS/400

Bits 6 & 7 (Setuid & Setgid):

\[\text{Ignored.}\]

In the interests of maintaining security under environments, which do support these bits; bits 6 and 7 shall be set to ZERO if any one of the following conditions are true:

- A file is created.
- The attributes/permissions associated with a file, are modified.
- A file is written to (the contents of the data associated with a file are modified).
- An Extended Attribute associated with the file is modified.
- A stream associated with a file is modified.

Bit 8 (Sticky):

\[\text{Ignored.}\]

\[\text{Shall be set to ZERO.}\]

Bit 10 (System):

\[\text{Ignored.}\]

\[\text{Shall be set to ZERO upon file creation only, otherwise maintained.}\]
3.3.3 File Entry

```c
struct FileEntry {
    struct tag DescriptorTag;
    struct icbtag ICBTag;
    Uint32 Uid;
    Uint32 Gid;
    Uint32 Permissions;
    Uint16 FileLinkCount;
    Uint8 RecordFormat;
    Uint8 RecordDisplayAttributes;
    Uint32 RecordLength;
    Uint64 InformationLength;
    Uint64 LogicalBlocksRecorded;
    struct timestamp AccessTime;
    struct timestamp ModificationTime;
    struct timestamp AttributeTime;
    Uint32 Checkpoint;
    struct long_ad ExtendedAttributeICB;
    struct EntityID ImplementationIdentifier;
    Uint64 UniqueID,
    Uint32 LengthofExtendedAttributes;
    Uint32 LengthofAllocationDescriptors;
    byte ExtendedAttributes[];
    byte AllocationDescriptors[];
}
```

NOTE: The total length of a FileEntry shall not exceed the size of one logical block.

3.3.3.1 Uint32 Uid

For operating systems that do not support the concept of a user identifier the implementation shall ignore this field. For operating systems that do support this field a value of $2^{32} - 1$ shall indicate an invalid UID, otherwise the field contains a valid user identifier.

For operating systems that do not support the concept of a user identifier the implementation shall set this field to $2^{32} - 1$ to indicate an invalid UID, unless otherwise specified by the user.

3.3.3.2 Uint32 Gid

For operating systems that do not support the concept of a group identifier the implementation shall ignore this field. For operating systems that do support this...
field a value of \(2^{32} - 1\) shall indicate an invalid GID, otherwise the field contains a valid group identifier.

For operating systems that do not support the concept of a group identifier the implementation shall set this field to \(2^{32} - 1\) to indicate an invalid GID, unless otherwise specified by the user.

### 3.3.3.3 Uint32 Permissions

```c
/* Definitions: */
/* Bit for a File for a Directory */
/* ------- ------------------------ ---------------------------- */
/* Execute May execute file May search directory */
/* Write May change file contents May create and delete files */
/* Read May examine file contents May list files in directory */
/* ChAttr May change file attributes May change dir attributes */
/* Delete May delete file May delete directory */
```

```c
#define OTHER_Execute 0x00000001
#define OTHER_Write   0x00000002
#define OTHER_Read    0x00000004
#define OTHER_ChAttr  0x00000008
#define OTHER_Delete  0x00000010
#define GROUP_Execute 0x00000020
#define GROUP_Write   0x00000040
#define GROUP_Read    0x00000080
#define GROUP_ChAttr  0x00000100
#define GROUP_Delete  0x00000200
#define OWNER_Execute 0x00000400
#define OWNER_Write   0x00000800
#define OWNER_Read    0x00001000
#define OWNER_ChAttr  0x00002000
#define OWNER_Delete  0x00004000
```

The concept of permissions that deals with security is not completely portable between operating systems. This document attempts to maintain consistency among implementations in processing the permission bits by addressing the following basic issues:

1. How should an implementation handle Owner, Group and Other permissions when the operating system has no concept of User and Group Ids?
2. How should an implementation process permission bits when encountered, specifically permission bits that do not directly map to an operating system supported permission bit?
3. What default values should be used for permission bits that do not directly map to an operating system supported permission bit when creating a new file?
Owner, Group and Other
In general, for operating systems that do not support User and Group Ids the following algorithm should be used when processing permission bits:

When reading a specific permission, the logical OR of all three (owner, group, other) permissions should be the value checked. For example a file would be considered writable if the logical OR of OWNER_Write, GROUP_Write and OTHER_Write was equal to one.

When setting a specific permission the implementation should set all three (owner, group, other) sets of permission bits. For example to mark a file as writable the OWNER_Write, GROUP_Write and OTHER_Write should all be set to one.

Default Permission Values
For the operating systems covered by this document the following table describes what default values should be used for permission bits that do not directly map to an operating system supported permission bit when creating a new file.

<table>
<thead>
<tr>
<th>Permission File/Directory</th>

</tr>
</tbody>
</table>

U - User Specified, 1 - Set, 0 - Clear

NOTE 1: Under UNIX only the owner of a file/directory may change its attributes. Under OS/400 if a file or directory is marked as writable (Write permission set) then the Attribute permission bit should be set.

NOTE 2: The Delete permission bit should be set based upon the status of the Write permission bit. Under DOS, OS/2 and Macintosh, if a file or directory is marked as writable (Write permission set) then the file is considered deletable and the Delete...
permission bit should be set. If a file is read only then the Delete permission bit should not be set. This applies to file create as well as changing attributes of a file.

Processing Permissions

Implementation shall process the permission bits according to the following table that describes how to process the permission bits under the operating systems covered by this document. The table addresses the issues associated with permission bits that do not directly map to an operating system supported permission bit.

<table>
<thead>
<tr>
<th>Permission</th>

</table>

E - Enforce, I - Ignore

The Execute bit for a directory, sometimes referred to as the search bit, has special meaning. This bit enables a directory to be searched, but not have its contents listed. For example assume a directory called PRIVATE exists which only has the Execute permission and does not have the Read permission bit set. The contents of the directory PRIVATE can not be listed. Assume there is a file within the PRIVATE directory called README. The user can get access to the README file since the PRIVATE directory is searchable.

To be able to list the contents of a directory both the Read and Execute permission bits must be set for the directory. To be able to create, delete and rename a file or subdirectory both the Write and Execute permission bits must be set for the directory.

To get a better understanding of the Execute bit for a directory reference any UNIX book that covers file and directory permissions. The rules defined by the Execute bit for a directory shall be enforced by all implementations. The exception to this rule applies to Macintosh implementations. A Macintosh implementation may ignore the status of the Read bit in determining the accessibility of a directory.
NOTE: To be able to delete a file or subdirectory the Delete permission bit for the file or subdirectory must be set, and both the Write and Execute permission bits must be set for the directory it occupies.

3.3.3.4 Uint64 UniqueID

NOTE: For some operating systems (i.e. Macintosh) this value needs to be less than the max value of a Int32 ($2^{31} - 1$). Under the Macintosh operating system this value is used to represent the Macintosh directory/file ID. Therefore an implementation should attempt to keep this value less than the max value of a Int32 ($2^{31} - 1$). The values 1-15 shall be reserved for the use of Macintosh implementations.

3.3.3.5 byte Extended Attributes

Certain extended attributes should be recorded in this field of the FileEntry for performance reasons. Other extended attributes should be recorded in an ICB pointed to by the field ExtendedAttributeICB. In the section on Extended Attributes it will be specified which extended attributes should be recorded in this field.

3.3.4 Extended Attributes

In order to handle some of the longer Extended Attributes (EAs) that may vary in length, the following rules apply to the EA space.

1. All EAs with an attribute length greater than or equal to a logical block shall be block aligned by starting and ending on a logical block boundary.
2. Smaller EAs shall be constrained to an attribute length that is a multiple of 4 bytes.
3. Each Extended Attributes Space shall appear as a single contiguous logical space constructed as follows:

<table>
<thead>
<tr>
<th>ECMA 167 EAs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non block aligned Implementation Use EAs</td>
</tr>
<tr>
<td>Block aligned Implementation Use EAs</td>
</tr>
<tr>
<td>Application Use EAs</td>
</tr>
</tbody>
</table>

NOTE: There may exist 2 Extended Attributes Spaces per file, one embedded in the File Entry or Extended File Entry and the other as a separate space referenced by the Extended Attribute ICB address in the File Entry or Extended File Entry. Each Extended Attributes Space, if present, must have its own Extended Attribute Header Descriptor (see the next section).
3.3.4.1 Extended Attribute Header Descriptor
struct ExtendedAttributeHeaderDescriptor { /* ECMA 167 4/14.10.1 */
    struct tag DescriptorTag;
    Uint32 ImplementationAttributesLocation;
    Uint32 ApplicationAttributesLocation;
};

A value in one of the location fields highlighted above equal to or greater than the length of the EA space shall be interpreted as an indication that the corresponding attribute does not exist.

If an attribute associated with one of the location fields highlighted above does not exist, then the value of the corresponding location field shall be set to #FFFFFFFF.

3.3.4.2 Alternate Permissions
struct AlternatePermissionsExtendedAttribute { /* ECMA 167 4/14.10.4 */
    Uint32 AttributeType;
    Uint8 AttributeSubtype;
    byte Reserved[3];
    Uint32 AttributeLength;
    Uint16 OwnerIdentification;
    Uint16 GroupIdentification;
    Uint16 Permission;
};

This structure shall not be recorded.

3.3.4.3 File Times Extended Attribute
struct FileTimesExtendedAttribute { /* ECMA 167 4/14.10.5 */
    Uint32 AttributeType;
    Uint8 AttributeSubtype;
    byte Reserved[3];
    Uint32 AttributeLength;
    Uint32 DataLength;
    Uint32 FileTimeExistence;
    byte FileTimes;
};

3.3.4.3.1 byte FileTimes
   A value in one of the fields highlighted above that is equal to or greater than the length of the EA space shall be interpreted as an indication that the corresponding attribute does not exist.

   If a file entry associated with one of the location fields highlighted above does not exist, then the value of the corresponding location field shall be set to #FFFFFFFF.
Extended File Entry, the file creation time in this structure shall be ignored and the file creation time from the main File Entry shall be used.

If the main File Entry is an Extended File Entry, this structure shall not be recorded with a file creation time.

If the main File Entry is not an Extended File Entry and the File Times Extended Attribute does not exist or does not contain the file creation time then an implementation shall use the Modification Time field of the File Entry to represent the file creation time.

3.3.4.4 Device Specification Extended Attribute

```
struct DeviceSpecificationExtendedAttribute { /* ECMA 167 4/14.10.7 */
    Uint32 AttributeType;
    Uint8 AttributeSubtype;
    byte Reserved[3];
    Uint32 AttributeLength;
    Uint32 ImplementationUseLength; /* (=IU_L) */
    Uint32 MajorDeviceIdentification;
    Uint32 MinorDeviceIdentification;
    byte ImplementationUse[IU_L];
}
```

The following paradigm shall be followed by an implementation that creates a Device Specification Extended Attribute associated with a file:

If and only if a file has a DeviceSpecificationExtendedAttribute associated with it, the contents of the FileType field in the icbtag structure shall be set to 6 (indicating a block special device file), OR 7 (indicating a character special device file).

If the contents of the FileType field in the icbtag structure do not equal 6 or 7, the DeviceSpecificationExtendedAttribute associated with a file shall be ignored.

In the event that the contents of the FileType field in the icbtag structure equals 6 or 7, and the file does not have a DeviceSpecificationExtendedAttribute associated with it, access to the file shall be denied.

For operating system environments that do not provide for the semantics associated with a block special device file, requests to open/read/write/close a
file that has the DeviceSpecificationExtendedAttribute associated with it shall be denied.

All implementations shall record a developer ID in the ImplementationUse field that uniquely identifies the current implementation.

### 3.3.4.5 Implementation Use Extended Attribute

```c
struct ImplementationUseExtendedAttribute { /* ECMA 167 4/14.10.8 */
    Uint32      AttributeType;
    Uint8       AttributeSubtype;
    byte        Reserved[3];
    Uint32      AttributeLength;
    Uint32      ImplementationUseLength; /* (=IU_L) */
    struct EntityID ImplementationIdentifier;
    byte        ImplementationUse[IU_L];
};
```

The AttributeLength field specifies the length of the entire extended attribute. For variable length extended attributes defined using the Implementation Use Extended Attribute the Attribute Length field should be large enough to leave padding space between the end of the Implementation Use field and the end of the Implementation Use Extended Attribute.

The following sections describe how the Implementation Use Extended Attribute is used under various operating systems to store operating system specific extended attributes.

The structures defined in the following sections contain a header checksum field. This field represents a 16-bit checksum of the Implementation Use Extended Attribute header. The fields AttributeType through ImplementationIdentifier inclusively represent the data covered by the checksum. The header checksum field is used to aid in disaster recovery of the extended attributes space. C source code for the header checksum may be found in the appendix.

**NOTE:** All compliant implementations shall preserve existing extended attributes encountered on the media. Implementations shall create and support the extended attributes for the operating system they currently support. For example, a Macintosh implementation shall preserve any OS/2 extended attributes encountered on the media. It shall also create and support all Macintosh extended attributes specified in this document.
3.3.4.5.1 All Operating Systems
3.3.4.5.1.1 FreeEASpace

This extended attribute shall be used to indicate unused space within the Extended Attributes Space. This extended attributes shall be stored as an Implementation Use Extended Attribute whose ImplementationIdentifier shall be set to:

"*UDF FreeEASpace"

The ImplementationUse area for this extended attribute shall be structured as follows:

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>Header Checksum</td>
<td>Uint16</td>
</tr>
<tr>
<td>2</td>
<td>IU_L-2</td>
<td>Free EA Space</td>
<td>bytes</td>
</tr>
</tbody>
</table>

This extended attribute allows an implementation to shrink/grow the total size of other extended attributes without rewriting the complete Extended Attributes Space. The FreeEASpace extended attribute may be overwritten and the space re-used by any implementation that sees a need to overwrite it.

3.3.4.5.1.2 DVD Copyright Management Information

This extended attribute shall be used to store DVD Copyright Management Information. This extended attribute shall be stored as an Implementation Use Extended Attribute whose ImplementationIdentifier shall be set to:

"*UDF DVD CGMS Info"

The ImplementationUse area for this extended attribute shall be structured as follows:

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>Header Checksum</td>
<td>Uint16</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>CGMS Information</td>
<td>byte</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>Data Structure Type</td>
<td>Uint8</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Protection System Information</td>
<td>bytes</td>
</tr>
</tbody>
</table>

This extended attribute allows DVD Copyright Management Information to be stored. The interpretation of this format shall be defined in the DVD specification published by the DVD Consortium (see 6.9.3). Support for this extended attribute is optional.
3.3.4.5.2 MS-DOS, Windows 95, Windows NT

Ignored.

Not supported. Extended attributes for existing files on the media shall be preserved.

3.3.4.5.3 OS/2

OS/2 supports an unlimited number of extended attributes, which shall be stored as a named stream as defined in 3.3.8.2. To enhance performance the following Implementation Use Extended Attribute will be created.

3.3.4.5.3.1 OS2EALength

This attribute specifies the OS/2 Extended Attribute Stream (3.3.8.2) information length. Since this value needs to be reported back to OS/2 under certain directory operations, for performance reasons it should be recorded in the ExtendedAttributes field of the FileEntry. This extended attribute shall be stored as an Implementation Use Extended Attribute whose ImplementationIdentifier shall be set to:

"*UDF OS/2 EALength"

The ImplementationUse area for this extended attribute shall be structured as follows:

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>Header Checksum</td>
<td>Uint16</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>OS/2 Extended Attribute Length</td>
<td>Uint32</td>
</tr>
</tbody>
</table>

The value recorded in the OS2ExtendedAttributeLength field shall be equal to the InformationLength field of the file entry for the OS2EA stream.

3.3.4.5.4 Macintosh OS

The Macintosh OS requires the use of the following extended attributes.

3.3.4.5.4.1 MacVolumeInfo

This extended attribute contains Macintosh volume information which shall be stored as an Implementation Use Extended Attribute whose ImplementationIdentifier shall be set to:

"*UDF Mac VolumeInfo"

The ImplementationUse area for this extended attribute shall be structured as follows:
### MacVolumeInfo format

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>Header Checksum</td>
<td>Uint16</td>
</tr>
<tr>
<td>2</td>
<td>12</td>
<td>Last Modification Date</td>
<td>timestamp</td>
</tr>
<tr>
<td>14</td>
<td>12</td>
<td>Last Backup Date</td>
<td>timestamp</td>
</tr>
<tr>
<td>26</td>
<td>32</td>
<td>Volume Finder Information</td>
<td>Uint32</td>
</tr>
</tbody>
</table>

The MacVolumeInfo extended attribute shall be recorded as an extended attribute of the root directory FileEntry.

### 3.3.4.5.4.2 MacFinderInfo

This extended attribute contains Macintosh Finder information for the associated file or directory. Since this information is accessed frequently, for performance reasons it should be recorded in the ExtendedAttributes field of the FileEntry.

The MacFinderInfo extended attribute shall be stored as an Implementation Use Extended Attribute whose ImplementationIdentifier shall be set to:

"*UDF Mac FinderInfo"

The ImplementationUse area for this extended attribute shall be structured as follows:

#### MacFinderInfo format for a directory

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>Header Checksum</td>
<td>Uint16</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>Reserved for padding</td>
<td>Uint16 = 0</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Parent Directory ID</td>
<td>Uint32</td>
</tr>
<tr>
<td>8</td>
<td>16</td>
<td>Directory Information</td>
<td>UDFDInfo</td>
</tr>
<tr>
<td>24</td>
<td>16</td>
<td>Directory Extended Information</td>
<td>UDFDXInfo</td>
</tr>
</tbody>
</table>

#### MacFinderInfo format for a file

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>Header Checksum</td>
<td>Uint16</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>Reserved for padding</td>
<td>Uint16 = 0</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Parent Directory ID</td>
<td>Uint32</td>
</tr>
<tr>
<td>8</td>
<td>16</td>
<td>File Information</td>
<td>UDFFInfo</td>
</tr>
<tr>
<td>24</td>
<td>16</td>
<td>File Extended Information</td>
<td>UDFFXInfo</td>
</tr>
<tr>
<td>40</td>
<td>4</td>
<td>Resource Fork Data Length</td>
<td>Uint32</td>
</tr>
<tr>
<td>44</td>
<td>4</td>
<td>Resource Fork Allocated Length</td>
<td>Uint32</td>
</tr>
</tbody>
</table>

The MacFinderInfo extended attribute shall be recorded as an extended attribute of every file and directory within the Logical Volume.
The following structures used within the *MacFinderInfo* structure are listed below for clarity. For complete information on these structures refer to the Macintosh books called “Inside Macintosh”. The volume and page number listed with each structure correspond to a specific “Inside Macintosh” volume and page.

**UDFPoint** format (Volume I, page 139)

<table>

<tr>
<td>12</td>
<td>4</td>
<td>FdPutAway</td>
<td>Int32</td>
</tr>
</tbody>
</table>

**NOTE:** The above-mentioned structures have their original Macintosh names preceded by “UDF” to indicate that they are actually different from the original Macintosh structures. On the media the UDF structures are stored little endian as opposed to the original Macintosh structures that are in big endian format.

3.3.4.5.5 UNIX

Ignored.

Not supported. Extended attributes for existing files on the media shall be preserved.

3.3.4.5.6 OS/400

OS/400 requires the use of the following extended attributes.

3.3.4.5.6.1 OS400DirInfo

This attribute specifies the OS/400 extended directory information. Since this value needs to be reported back to OS/400 for normal directory information processing, for performance reasons it should be recorded in the ExtendedAttributes field of the FileEntry. This extended attribute shall be stored as an Implementation Use Extended Attribute whose ImplementationIdentifier shall be set to:

```
"*UDF OS/400 DirInfo"
```

The ImplementationUse area for this extended attribute shall be structured as follows:

**OS400DirInfo** format

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>Header Checksum</td>
<td>Uint16</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>Reserved for padding</td>
<td>Uint16 = 0</td>
</tr>
<tr>
<td>4</td>
<td>44</td>
<td>DirectoryInfo</td>
<td>bytes</td>
</tr>
</tbody>
</table>
For complete information on the structure of the DirectoryInfo field recorded in the OS400DirInfo format, refer to the following IBM document:

IBM OS/400 UDF Implementation
Optical Storage Solutions, Department HTT
IBM
Rochester, Minnesota

3.3.4.6 Application Use Extended Attribute

```
struct ApplicationUseExtendedAttribute { /* ECMA 167 4/14.10.9 */
    Uint32          AttributeType;    /* = 65536 */
    Uint8          AttributeSubtype;
    byte           Reserved[3];
    Uint32         AttributeLength;
    Uint32         ApplicationUseLength; /* (=AU_L) */
    struct EntityID ApplicationIdentifier;
    byte           ApplicationUse[AU_L];
}
```

The AttributeLength field specifies the length of the entire extended attribute. For variable length extended attributes defined using the Application Use Extended Attribute the Attribute Length field should be large enough to leave padding space between the end of the ApplicationUse field and the end of the Application Use Extended Attribute.

The structures defined in the following section contain a header checksum field. This field represents a 16-bit checksum of the Application Use Extended Attribute header. The fields AttributeType through ApplicationIdentifier inclusively represent the data covered by the checksum. The header checksum field is used to aid in disaster recovery of the extended attributes space. C source code for the header checksum may be found in the appendix.

**NOTE:** All compliant implementations shall preserve existing extended attributes encountered on the media. Implementations shall create and support the extended attributes for the operating system they currently support. For example, a Macintosh implementation shall preserve any OS/2 extended attributes encountered on the media. It shall also create and support all Macintosh extended attributes specified in this document.

3.3.4.6.1 All Operating Systems

This extended attribute shall be used to indicate unused space within the Extended Attributes Space reserved for Application Use Extended Attributes. This extended
attribute shall be stored as an Application Use Extended Attribute whose ApplicationIdentifier shall be set to:
“*UDF FreeAppEASpace”

The ApplicationUse area for this extended attribute shall be structured as follows:

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>Header Checksum</td>
<td>Uint16</td>
</tr>
<tr>
<td>2</td>
<td>IU_L-2</td>
<td>Free EA Space</td>
<td>bytes</td>
</tr>
</tbody>
</table>

This extended attribute allows an implementation to shrink/grow the total size of other extended attributes without rewriting the complete Extended Attributes Space. The FreeAppEASpace extended attribute may be overwritten and the space re-used by any implementation who sees a need to overwrite it.

### 3.3.5 Named Streams

Named streams provide a mechanism for associating related data of a file. It is similar in concept to extended attributes. However, named streams have significant advantages over extended attributes. They are not as limited in length. Space management is much easier as each stream has its own space, rather than the common space of extended attributes. Finding a particular stream does not involve searching the entire data space, as it does for extended attributes.

Named streams are mainly intended for user data. For example, a database application may store the records in the default or mainstream and indices in named streams. The user would then see only one file for the database rather than many, and the application can use the various streams almost as if they were independent files.

Named Streams are identified by an Extended File Entry. Extended File Entries are required for files with associated named streams. Files without named streams should use Extended File Entries. Files may have normal File Entries; normal File Entries would be used where backward compatibility is desired, such as writing DVD Video discs.

There is a “System Stream Directory” which is the stream directory identified by the File Set Descriptor. These streams are used to describe data related to the entire medium instead of data that relates to a file. UDF defines several “system streams” that are to be identified by the system stream directory.

The parent of the System Stream Directory shall be the system stream directory.
It is recommended that Named Streams be used to store metadata and application data instead of Extended Attributes in new implementations.

3.3.5.1 Named Streams Restrictions
ECMA 167 3rd edition defines a new File Entry that contains a field for identifying a stream directory. This new File Entry should be used in place of the old File Entry, and should be used for describing the streams themselves. Old and new file entries may be freely mixed. In particular, compatibility with old reader implementations can be maintained for certain files.

Restrictions:

The stream directory ICB field of ICBs describing stream directories or named streams shall be set to zero. [no hierarchical streams]

Each named stream shall be identified by exactly one FID in exactly one Stream Directory. [no hard links among named streams or files and named streams]

Each Stream Directory ICB shall be identified by exactly one Stream Directory ICB field. [no hard links to stream directories]. The sole exception is that the parent of the system stream directory shall be the system stream directory.

Hard Links to files with named streams are allowed.

Named Streams and Stream Directories shall not have Extended Attributes.

The Unique ID field of Named Streams and Stream Directories shall be the same as the Unique ID of the main data stream.
The UID, GID, and permissions fields of the main File Entry shall apply to all named streams associated with the main stream. At the time of creation of a named stream the values of the UID, GID and permissions fields of the main file entry should be used as the default values for the corresponding fields of the named stream. Implementations are not required to maintain or check these fields in a named stream.

Implementations should not present streams marked with the metadata bit set in the FID to the user. Streams marked with the metadata bit are intended solely for the use of the file system implementation.

The parent entry FID in a stream directory points to the main Extended File Entry, so its reference must be counted in the Link Count field of the Extended File Entry. The sole exception is that the parent of the system stream directory shall be the system stream directory.

*Note:* There is a potential pitfall when deleting files/directories: if the link count goes to one when a FID is deleted, implementations must check for the presence of a stream directory. If present, there are no more FIDs pointing to this File Entry, so it and all associated structures must be deleted.

The modification time field of the main Extended File Entry should be updated whenever any associated named stream is modified. The Access Time field of the main Extended File Entry should be updated whenever any associated named stream is accessed. The SETUID and SETGID bits of the ICB Tag flags field in the main Extended File Entry should be cleared whenever any associated named stream is modified.

The ICB for a Named Stream directory shall have a file type of 13. All named streams shall have a file type of 5.

All systems shall make the main data stream available, even on implementations that do not implement named streams.

### 3.3.5.2 System Named Streams (Metadata)

A set of named streams is defined by UDF for file system use. Some UDF named streams are identified by the File Set Descriptor and apply to the entire file set (*System Stream Directory*). Others pertain to individual files or directories and are identified by the stream directory.

All UDF named streams shall have the Metadata bit set in the File Identifier Descriptor in the Stream Directory, unless otherwise specified in this document. All streams not generated by the file system implementation shall have this bit set to zero.

All UDF named streams shall have a file type of 5 in the ICB identifying the stream.
The four characters *UDF are the first four characters of all UDF defined named streams in this document. Implementations shall not use any identifier beginning with *UDF for named streams that are not defined in this document. All identifiers for named streams beginning with *UDF are reserved for future definition by OSTA.

### 3.3.6 Extended Attributes as named streams

An extended attribute may be recorded as a named stream instead. The extended attribute is converted according to the following rules:

The stream is marked as a Metadata stream.

The EA header and Header Checksum are not recorded. If the EA included pad bytes between the Header Checksum and the remaining data, these are also not recorded.

Any extended attribute of a file or directory can be converted to a stream of the same file or directory by the following algorithm:

1. Create a stream for the file or directory containing the extended attribute. The identifier specified for the Entity Identifier becomes the stream name.
2. Copy the data of the extended attribute into the stream.
3. Delete the extended attribute.

### 3.3.7 UDF Defined System Streams

This section contains the definition of UDF defined system streams.

<table>
<thead>
<tr>
<th>Stream Name</th>
<th>Stream Location</th>
<th>Metadata Flag</th>
</tr>
</thead>
<tbody>
<tr>
<td>*<em>&quot;<em>UDF Unique ID Mapping Data&quot;</em></em></td>
<td>System Stream Directory (File Set Descriptor)</td>
<td>1</td>
</tr>
<tr>
<td>*<em>&quot;<em>UDF Non-Allocatable Space&quot;</em></em></td>
<td>System Stream Directory (File Set Descriptor)</td>
<td>1</td>
</tr>
<tr>
<td>*<em>&quot;<em>UDF Power Cal Table&quot;</em></em></td>
<td>System Stream Directory (File Set Descriptor)</td>
<td>1</td>
</tr>
<tr>
<td>*<em>&quot;<em>UDF Backup&quot;</em></em></td>
<td>System Stream Directory (File Set Descriptor)</td>
<td>1</td>
</tr>
</tbody>
</table>

Since the streams listed above have the Metadata flag set, the implementation shall not pass the name of the stream across the “plug-in file system interface” of a platform.

#### 3.3.7.1 UniqueID Mapping Data Stream

The Unique ID Mapping Data allows an implementation to go directly to the ICB hierarchy for the file/directory associated with a UDFUniqueId, or to the ICB hierarchy for the directory which contains the file/directory associated with the UDFUniqueId. Unique ID Mapping Data is stored as a named stream of the *System Stream Directory* (associated with the File Set Descriptor). The name of this stream shall be set to:
“*UDF Unique ID Mapping Data*”

The Metadata bit in the File Characteristics field of the File Identifier Descriptor shall be set to 1 to indicate that the existence of this file should not be made known to clients of a platform’s file system interface.

- Shall be created for read-only media
- Shall be created by implementations which batch write (e.g., pre-mastering tools) a volume on write-once and rewritable media
- For implementations which perform incremental updates of volumes on write-once or rewritable media (e.g., on-line file systems), the following rules apply:
  - May be created and maintained if not present
  - Shall be maintained if present and volume is clean
  - Should be repaired and maintained, but may be deleted, if present and volume is dirty
- For these rules, a volume is clean if either a valid Close Logical Volume Integrity Descriptor or a valid Virtual Allocation Table is recorded

### 3.3.7.1.1 UDF Unique ID Mapping Data

The contents of the Unique ID Mapping stream are described by the table “UDF Unique ID Mapping Data” which contains some header fields before an array of “UDF Unique ID Mapping Entry.” The fields of these structures are described below their corresponding table.

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>32</td>
<td>Implementation Identifier</td>
<td>EntityID</td>
</tr>
<tr>
<td>32</td>
<td>4</td>
<td>Flags</td>
<td>Uint32</td>
</tr>
<tr>
<td>36</td>
<td>4</td>
<td>Mapping Entry Count (MEC)</td>
<td>Uint32</td>
</tr>
<tr>
<td>40</td>
<td>8</td>
<td>Reserved</td>
<td>Bytes (= #00)</td>
</tr>
<tr>
<td>48</td>
<td>16*MEC</td>
<td>Mapping Entries</td>
<td>IDMappingEntry</td>
</tr>
</tbody>
</table>

**Implementation Identifier** is described in section 2.1.5.

**Flags** are defined as follows:

Bit 0, if set to ONE, shall mean UDF Unique ID, once decremented by 16 (the value NextUniqueID is initialized to), can be used as an index into the array Mapping Entries. Blank entries, if present, are all beyond the last array element with a UDF Unique ID.

Bits 1 – 31, reserved, shall be set to ZERO.

**Mapping Entry Count** is the size, in entries, of the array Mapping Entries.

**Mapping Entries** is an array of UDF Unique ID Mapping Entry structures. There is one mapping entry for every non-stream, non-parent File Identifier Descriptor.
Whenever the volume is consistent, the array is always sorted in ascending order of UDF Unique ID. Except as limited by the flags, blank entries are allowed anywhere in the array, and entries are not required to have a UDF Unique ID value of one more than the preceding entry. A blank entry has a value of ZERO in all fields.

3.3.7.1.2 UDF Unique ID Mapping Entry

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>UDFUnique ID</td>
<td>Uint32</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Parent Logical Block Number</td>
<td>Uint32</td>
</tr>
<tr>
<td>8</td>
<td>4</td>
<td>Object Logical Block Number</td>
<td>Uint32</td>
</tr>
<tr>
<td>12</td>
<td>2</td>
<td>Parent Partition Reference Number</td>
<td>Uint16</td>
</tr>
<tr>
<td>14</td>
<td>2</td>
<td>Object Partition Reference Number</td>
<td>Uint16</td>
</tr>
</tbody>
</table>

UDF Unique ID is the value found in a FID for the file or directory.

Parent Logical Block Number is the logical block number of the ICB identifying the directory that contains the FID identifying the object.

Object Logical Block Number is the logical block number of the ICB identifying this object.

Parent Partition Reference Number is the partition reference number from the long_ad of the ICB field in the parent in the same directory containing the FID for this file or directory.

Object Partition Reference Number is the partition reference number from the long_ad of the ICB field in the FID with this UDFUniqueID.

3.3.7.2 Non-Allocatable Space Stream

ECMA 167 does not provide for a mechanism to describe defective areas on media or areas not usable due to allocation outside of the file system. The Non-Allocatable Space Stream provides a method to describe space not usable by the file system. The Non-Allocatable Space Stream shall be recorded only on media systems that do not do defect management (eg. CD-RW).

The Non-Allocatable Space Stream shall be generated at format time. All space indicated by the Non-Allocatable Space Stream shall also be marked as allocated in the free space map. The Non-Allocatable Space Stream shall be recorded as a named stream in the system stream directory of the File Set Descriptor. The stream name shall be:
“*UDF Non-Allocatable Space*”

The stream shall be marked with the attributes *Metadata* (bit 4 of file characteristics set to ONE) and System (bit 10 of ICB flags field set to ONE). This stream shall have all Non-Allocatable sectors identified by its allocation extents. The allocation extents shall indicate that each extent is allocated but not recorded. This list shall include both defective sectors found at format time and space allocated for sparing at format time.

NOTE: For packetized media all blocks of a packet containing a defect should be allocated to the Non-Allocatable Space Stream.

### 3.3.7.3 Power Calibration Stream

One of the potential limitations on the effective use of the packet-write capabilities of CD-Recordable drives is the limited number (100) of power calibration areas available on current CD-R media. These power calibration areas are used to establish the appropriate power calibration settings with which data can be successfully and reliably written to the CD-R disc currently in the drive. The appropriate settings for a specific drive can vary significantly from disc to disc, between two different drives of the same make and model, and even using the same disc, drive and system configuration, but under different environmental conditions.

Because of this, most current CD-R drives recalibrate themselves the first time a write is attempted after a media change has occurred. This imposes no restriction on recording to discs using the disc-at-once or track-at-once modes, since in each of these modes the disc will fill (either by consuming the total available data capacity or total number of recordable tracks) in less than 100 separate writes. When using packet-write though, the disc could be written to thousands of times over an extended period before the disc is full.

Suppose, for instance, one wanted to incrementally back-up any new and/or modified files at the end of each work day (though the drive might also be used intermittently to do other projects during the day). These back-ups may require writing as little as a megabyte (or even less) each day. If one of the power calibration areas is used to calibrate the drive before writing to the disc every day, within five months the power calibration areas will all have been used, but only a small fraction of the total disc capacity will have been consumed. It is likely that such a result would be both unexpected and unacceptable to the user of such a product.

The industry is attempting to provide ways to reduce the frequency with which the power calibration area of a CD-Recordable disc must be used. At least one current CD-R drive model tries to remember the power calibration values last used for recording data on each of a small number of recently encountered discs. Most CD-Recordable drives provide a mechanism for the host software to retrieve from the drive the most recent power calibration settings used by the drive to record data on the current disc, and to restore and use such information at some future time.
The Power Calibration Table described herein would be used to store on the disc the power calibration information thus obtained for future use by compatible implementations. The table consists of a header followed by a list of records containing power calibration settings which have been used by various drives and/or hosts, under various conditions, to record data on this disc, as well as other relevant information which may be used to determine which of the recorded calibration settings may be appropriate for use in a future situation. While every effort has been made to anticipate and include all necessary information to make effective use of the recorded power calibration information possible, it is up to the individual implementation to determine if, when and how such information will actually be used.

The Power Calibration Table may be recorded as a system stream of the File Set Descriptor according to the rules of 3.3.5. The name of the stream shall be as follows:

“*UDF Power Cal Table”

Implementations that do not support the Power Calibration Table shall not delete this stream. Further, any implementation which supports and/or uses the Power Calibration Table shall not delete or modify any records from such table which the implementation, through its use thereof, did not clearly and specifically obsolete or update.
The stream shall be formatted as follows:

### 3.3.7.3.1 Power Calibration Table Stream

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>32</td>
<td>Implementation Identifier</td>
<td>EntityID [ UDF 2.1.5]</td>
</tr>
<tr>
<td>32</td>
<td>4</td>
<td>Number of Records</td>
<td>Uint32 [1/7.1.5]</td>
</tr>
<tr>
<td>36</td>
<td>*</td>
<td>Power Calibration Table Records</td>
<td>bytes</td>
</tr>
</tbody>
</table>

**Implementation Identifier:**
See UDF section 2.1.5.

**Number of Records:**
Shall specify the number of records contained in the power calibration table

**Power Calibration Table Records:**
A series of power calibration table records for drives which have written to this disc. The length of this table is variable, but shall be a multiple of four bytes. Recording of data in any unstructured field shall be left justified and padded on the right with #20 bytes.

#### Power Calibration Table Record Layout

<table>
<thead>
<tr>
<th>RBP</th>

<td>Speed</td>
<td>Uint16 [1/7.1.3]</td>
</tr>
<tr>
<td>106</td>
<td>6</td>
<td>Power Calibration Values</td>
<td>bytes</td>
</tr>
<tr>
<td>112</td>
<td>[DUA_L]</td>
<td>Drive Unique Area</td>
<td>bytes</td>
</tr>
</tbody>
</table>

**Record Length** – The length of this Power Calibration Table Record in bytes, including the optional variable length Drive Unique Area. Shall be a multiple of four bytes.

**Drive Unique Area Length** – The length of the optional Drive Unique Area recorded at the end of this record in bytes. Shall be a multiple of four bytes.
Vendor ID – The Vendor ID reported by the drive.

Product ID – The Product ID reported by the drive.

Firmware Revision Level – The Firmware Revision Level reported by the drive.

Serial Number/Device Unique ID – A serial number or other unique identifier for the specific drive, of the model specified by the vendor and product IDs given, which has successfully used the power calibration values reported herein to record data on this disc.

Host ID – The host serial number, ethernet ID, or other value (or combination of values) used by an implementation to identify the specific host computer to which the drive was attached when it successfully used the power calibration values reported herein to record data on this disc. An implementation shall attempt to provide a unique value for each host, but is not required to guarantee the value’s uniqueness.

Originating Time Stamp – The date and time at which the power calibration values recorded herein were initially verified to have been successfully used.

Updated Time Stamp – The date and time at which the power calibration values recorded herein were most recently verified to have been successfully used.

Speed – The recording speed, as reported by the drive, at which power calibration values recorded herein were successfully used. This value is the number of kilobytes per second (bytes per second / 1000) that the data was written to the disc by the drive (truncating any fractions). For example, a speed of 176 means data was written to the disc at 176 Kbytes/second, which is the basic CD-DA (Digital Audio) data rate (a.k.a. “1X” for CD-DA). A speed of 353 means data was written to the disc at 353 Kbytes/second, or twice the basic CD-DA data rate (a.k.a. “2X” for CD-DA). CD-ROM recording rates should be adjusted upward (roughly 15%) to the corresponding CD-DA rates to determine the correct speed value (e.g. A “1X” CD-ROM data rate should be recorded as a “1X” CD-DA, which is a speed of 176). Note that these are raw data rates and do not reflect all overhead resulting from (additional) headers, error correction data, etc.

Power Calibration Values – The vendor-specific power calibration values reported by the drive.
Drive Unique Area – Optional area for recording unrestricted information unique to the drive (such as drive operating temperature), which certain implementations may use to enhance the use of the recorded power calibration information or the operation of the associated drive. The drive manufacturer shall define recording of data in this field. This area shall be an integral multiple of four bytes in length.

3.3.7.4 UDF Backup Time
The name of this stream shall be set to:

“*UDF Backup”

This stream shall have the following contents, which should be embedded in the ICB:

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>12</td>
<td>Backup Time</td>
<td>timestamp</td>
</tr>
</tbody>
</table>

Backup Time is the latest time that a backup of this volume was performed.

3.3.8 UDF Defined Non-System Streams
This section defines the following non-system streams:

<table>
<thead>
<tr>
<th>Stream Name</th>
<th>Stream Location</th>
<th>Metadata Flag</th>
</tr>
</thead>
<tbody>
<tr>
<td>“*UDF Macintosh Resource Fork”</td>
<td>Any file</td>
<td>0</td>
</tr>
<tr>
<td>“*UDF OS/2 EA”</td>
<td>Any file or directory</td>
<td>0</td>
</tr>
<tr>
<td>“*UDF NT ACL”</td>
<td>Any file or directory</td>
<td>0</td>
</tr>
<tr>
<td>“*UDF UNIX ACL”</td>
<td>Any file or directory</td>
<td>0</td>
</tr>
</tbody>
</table>

3.3.8.1 Macintosh Resource Fork Stream
Because the Resource Fork is referenced by an explicit interface, UDF implementations are not provided the authoritative name for this stream. For the purpose of interchange, the name shall be set to:

“*UDF Macintosh Resource Fork”

The Metadata bit in the File Characteristics field of the File Identifier Descriptor shall be set to 0 to indicate that the existence of this file should be made known to clients of a platform’s file system interface.
3.3.8.2 OS/2 EA Stream
All OS/2 definable extended attributes shall be stored as a named stream whose name shall be set to:

“*UDF OS/2 EA”

The OS2EA Stream contains a table of OS/2 Full EAs (FEA) as shown below.

<table>
<thead>
<tr>
<th>RBP</th>
<th>Length</th>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Flags</td>
<td>Uint8</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Length of Name (=L_N)</td>
<td>Uint8</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>Length of Value (=L_V)</td>
<td>Uint16</td>
</tr>
<tr>
<td>4+L_N</td>
<td>L_V</td>
<td>Name</td>
<td>bytes</td>
</tr>
<tr>
<td>4+L_N</td>
<td>L_V</td>
<td>Value</td>
<td>bytes</td>
</tr>
</tbody>
</table>

For a complete description of Full EAs (FEA) please reference the following IBM document:

“Installable File System for OS/2 Version 2.0”
OS/2 File Systems Department
PSPC Boca Raton, Florida
February 17, 1992

3.3.8.3 Access Control Lists
Certain operating systems support the concept of Access Control Lists (ACLs) for enforcing file access restrictions. In order to facilitate support for ACL’s UDF has defined a set of system level named streams, whose purpose is to store the ACL associated with a given file object.

ACLs under UDF are stored as named streams, following the rules of section 3.3.5. The contents of the named stream ACL shall be opaque and are not defined by this document. Interpretation of the contents of the named ACL shall be left to the operating system for which the ACL is intended. The following names shall be used to identify the ACLs and shall be reserved. These names shall not be used for application named streams.

“*UDF NT ACL”

This name shall identify the named stream ACL for the Windows NT operating system.

“*UDF UNIX ACL”

This name shall identify the named stream ACL for the UNIX operating system.
4. User Interface Requirements

4.1 Part 3 – Volume Structure

Part 3 of ECMA 167 contains various Identifiers which, depending upon the implementation, may have to be presented to the user.

- VolumeIdentifier
- VolumeSetIdentifier
- LogicalVolumeID

These identifiers, which are stored in CS0, may have to go through some form of translation to be displayable to the user. Therefore when an implementation must perform an OS specific translation on the above listed identifiers the implementation shall use the algorithms described in section 4.2.2.1.

C source code for the translation algorithms may be found in the appendices of this document.

4.2 Part 4 – File System

4.2.1 ICB Tag

```c
struct icbtag {
    /* ECMA 167 4/14.6 */
    Uint32 PriorRecordedNumberOfDirectEntries;
    Uint16 StrategyType;
    byte StrategyParameter[2];
    Uint16 NumberOfEntries;
    byte Reserved; /* == #00 */
    Uint8 FileType;
    Lb_addr ParentICBLocation;
    Uint16 Flags;
}
```

4.2.1.1 FileType

Any open/close/read/write requests for file(s) that have any of the following values in this field shall result in an Access Denied error condition under non-UNIX operating system environments:

FileType values – 0 (Unknown), 6 (block device), 7 (character device), 9 (FIFO), and 10 (C_ISSOCK).
Any open/close/read/write requests to a file of type 12 (SymbolicLink) shall access the file/directory to which the symbolic link is pointing.

4.2.2 File Identifier Descriptor

struct FileIdentifierDescriptor {
    struct tag DescriptorTag;
    Uint16 FileVersionNumber;
    Uint8 FileCharacteristics;
    Uint8 LengthofFileIdentifier;
    struct long_ad ICB;
    Uint16 LengthofImplementationUse;
    byte ImplementationUse[];
    char FileIdentifier[];
    byte Padding[];
}

4.2.2.1 char FileIdentifier

Since most operating systems have their own specifications as to characteristics of a legal FileIdentifier, this becomes a problem with interchange. Therefore since all implementations must perform some form of FileIdentifier translation it would be to the users advantage if all implementations used the same algorithm.

The problems with FileIdentifier translations fall within one or more of the following categories:

- **Name Length** – Most operating systems have some fixed limit for the length of a file identifier.

- **Invalid Characters** – Most operating systems have certain characters considered as being illegal within a file identifier name.

- **Displayable Characters** – Since UDF supports the Unicode character set standard characters within a file identifier may be encountered which are not displayable on the receiving system.

- **Case Insensitive** – Some operating systems are case insensitive in regards to file identifiers. For example OS/2 preserves the original case of the file identifier when the file is created, but uses a case insensitive operations when accessing the file identifier. In OS/2 “Abc” and “ABC” would be the same file name.
• **Reserved Names** – Some operating systems have certain names that cannot be used for a file identifier name.

The following sections outline the *FileIdentifier* translation algorithm for each specific operating system covered by this document. This algorithm shall be used by all OSTA UDF compliant implementations. The algorithm only applies when reading an illegal *FileIdentifier*. The original *FileIdentifier* name on the media should not be modified. This algorithm shall be applied by any implementation that performs some form of *FileIdentifier* translation to meet operating system file identifier restrictions.

All OSTA UDF compliant implementations shall support the UDF translation algorithms, but may support additional algorithms. If multiple algorithms are supported the user of the implementation shall be provided with a method to select the UDF translation algorithms. It is recommended that the default displayable algorithm be the UDF defined algorithm.

The primary goal of these algorithms is to produce a *unique* file name that meets the specific operating system restrictions without having to scan the entire directory in which the file resides.

C source code for the following algorithms may be found in the appendices of this document.

**NOTE:** In the definition of the following algorithms anytime a d-character is specified in quotes, the Unicode hexadecimal value will also be specified. The following algorithms reference “CS0 Hex representation”, which corresponds to using the Unicode values #0030 - #0039, and #0041 - #0046 to represent a value in hex. In addition, the following algorithms reference “CS0 Base41 representation”, which corresponds to augmenting the CS0 Hex representation to use #0047 - #005A, #0023, #005F, #007E, #002D and #0040 to represent digits 16-40.

The following algorithms could still result in name-collisions being reported to the user of an implementation. However, the rationale includes the need for efficient access to the contents of a directory and consistent name translations across logical volume mounts and file system driver implementations, while allowing the user to obtain access to any file within the directory (through possibly renaming a file).

Some name transformations in section 4.2.2.1 result in two namespaces being visible at once in a given directory – the space of primary names, those which are physically recorded in a directory; and the space of generated names, those which are derived from the primary names. This is distinct from transformations that take an otherwise illegal name and render it into a legal form, the illegal name not being considered part of the namespace of the directory on that system. For UDF implementations using such
transforms, the implementation should search a directory in two passes: pass one should match against the primary namespace and pass two should match against the generated namespace. A match in the primary namespace should be preferred to a match against the generated namespace.

Definitions:
A FileIdentifier shall be considered as being composed of two parts, a file name and file extension.

The character ‘.’ (#002E) shall be considered as the separator for the FileIdentifier of a file; characters appearing subsequent to the last ‘.’ (#002E) shall be considered as constituting the file extension if and only if it is less than or equal to 5 characters in length, otherwise the file extension shall not exist. Characters appearing prior to the file extension, excluding the last ‘.’ (#002E), shall be considered as constituting the file name.

NOTE: Even though OS/2, Macintosh, and UNIX do not have an official concept of a filename extension it is common file naming conventions to end a file with “.” Followed by a 1 to 5 character extension. Therefore the following algorithms attempt to preserve the file extension up to a maximum of 5 characters.

4.2.2.1.1 MS-DOS
Due to the restrictions imposed by the MS DOS operating system environments on the FileIdentifier associated with a file the following methodology shall be employed to handle FileIdentifier(s) under the above-mentioned operating system environments.

Exception: Implementations on non-MS-DOS systems that may normally provide dual namespaces (8.3 and non-8.3) using this transformation may omit or provide a mechanism for disabling its use.

Restrictions: The file name component of the FileIdentifier shall not exceed 8 characters. The file extension component of the FileIdentifier shall not exceed 3 characters.

1. FileIdentifier Lookup: Upon request for a “lookup” of a FileIdentifier, a case-insensitive comparison shall be performed.
2. Validate FileIdentifier: If the FileIdentifier is a valid MS-DOS file identifier then do not apply the following steps.
3. Remove Spaces: All embedded spaces within the identifier shall be removed.
4. Invalid Characters: A FileIdentifier that contains characters considered invalid within a file name or file extension (as defined above), or not
displayable in the current environment, shall have them translated into “_” (#005F). (the file identifier on the media is NOT modified). Multiple sequential invalid or non-displayable characters shall be translated into a single “_” (#005F) character. Reference the appendix on invalid characters for a complete list.

5. **Leading Periods:** In the event that there do not exist any characters prior to the first “.” (#002E) character, leading “.” (#002E) characters shall be disregarded up to the first non “.” (#002E) character, in the application of this heuristic.

6. **Multiple Periods:** In the event that the *FileIdentifier* contains multiple “.” (#002E) characters, all characters appearing subsequent to the last ‘.’ (#002E) shall be considered as constituting the *file extension* if and only if it is less than or equal to 5 characters in length, otherwise the *file extension* shall not exist. Characters appearing prior to the *file extension*, excluding the last ‘.’ (#002E), shall be considered as constituting the *file name*. All embedded “.” (#002E) characters within the *file name* shall be removed.

7. **Long Extension:** In the event that the number of characters constituting the *file extension* at this step in the process is greater than 3, the *file extension* shall be regarded as having been composed of the first 3 characters amongst the characters constituting the *file extension* at this step in the process.

8. **Long Filename:** In the event that the number of characters constituting the *file name* at this step in the process is greater than 8, the *file name* shall be truncated to 4 characters.

9. **FileIdentifier CRC:** Since through the above process character information from the original *FileIdentifier* is lost the chance of creating a duplicate *FileIdentifier* in the same directory increases. To greatly reduce the chance of having a duplicate *FileIdentifier* the file name shall be modified to contain a CRC of the original *FileIdentifier*. The *file name* shall be composed of the first 4 characters constituting the *file name* at this step in the process, followed by the separator ‘#’ (#0023), followed by the 3 digit CS0 Base41 representation of the 16-bit CRC of the UNICODE expansion of the original filename.

10. The new file identifier shall be translated to all upper case.

4.2.2.1.2 OS/2

Due to the restrictions imposed by the OS/2 operating system environment, on the *FileIdentifier* associated with a file the following methodology shall be employed to handle *FileIdentifier(s)* under the above-mentioned operating system environment:

1. **FileIdentifier Lookup:** Upon request for a “lookup” of a *FileIdentifier*, a case-sensitive comparison may be performed. If the case-sensitive
comparison is not done or if it fails, a case-insensitive comparison shall be performed.

2. Validate FileIdentifier: If the FileIdentifier is a valid OS/2 file identifier then do not apply the following steps.

3. Invalid Characters: A FileIdentifier that contains characters considered invalid within an OS/2 file name, or not displayable in the current environment shall have them translated into “_” (#005F). Multiple sequential invalid or non-displayable characters shall be translated into a single “_” (#005F) character. Reference the appendix on invalid characters for a complete list.

4. Trailing Periods and Spaces: All trailing “.” (#002E) and “_” (#0020) shall be removed.

5. FileIdentifier CRC: Since through the above process character information from the original FileIdentifier is lost the chance of creating a duplicate FileIdentifier in the same directory increases. To greatly reduce the chance of having a duplicate FileIdentifier the file name shall be modified to contain a CRC of the original FileIdentifier.

If there is a file extension then the new FileIdentifier shall be composed of up to the first (254 – (length of (new file extension)) + 1 (for the ‘.’)) – 5 (for the #CRC)) characters constituting the file name at this step in the process, followed by the separator ‘#’ (#0023); followed by a 4 digit CS0 Hex representation of the 16-bit CRC of the original CS0 FileIdentifier, followed by ‘.’ (#002E) and the file extension at this step in the process.

Otherwise if there is no file extension the new FileIdentifier shall be composed of up to the first (254 – 5 (for the #CRC)) characters constituting the file name at this step in the process. Followed by the separator ‘#’ (#0023); followed by a 4 digit CS0 Hex representation of the 16-bit CRC of the original CS0 FileIdentifier.

4.2.2.1.3 Macintosh

Due to the restrictions imposed by the Macintosh operating system environment, on the FileIdentifier associated with a file the following methodology shall be employed to handle FileIdentifier(s) under the above-mentioned operating system environment:

1. FileIdentifier Lookup: Upon request for a “lookup” of a FileIdentifier, a case-sensitive comparison may be performed. If the case-sensitive comparison is not done or if it fails, a case-insensitive comparison shall be performed.

2. Validate FileIdentifier: If the FileIdentifier is a valid Macintosh file identifier then do not apply the following steps.
3. **Invalid Characters**: A *FileIdentifier* that contains characters considered invalid within a Macintosh file name, or not displayable in the current environment, shall have them translated into “_” (#005F). Multiple sequential invalid or non-displayable characters shall be translated into a single “_” (#005F) character. Reference the appendix on invalid characters for a complete list.

4. **Long FileIdentifier** – In the event that the number of characters constituting the *FileIdentifier* at this step in the process is greater than 31 (maximum name length for the Macintosh operating system), the new *FileIdentifier* will consist of the first 26 characters of the *FileIdentifier* at this step in the process.

5. **FileIdentifier CRC** Since through the above process character information from the original *FileIdentifier* is lost the chance of creating a duplicate *FileIdentifier* in the same directory increases. To greatly reduce the chance of having a duplicate *FileIdentifier* the file name shall be modified to contain a CRC of the original *FileIdentifier*.

   If there is a *file extension* then the new *FileIdentifier* shall be composed of up to the first (31 – (length of (new file extension) + 1 (for the ‘.’))) – 5 (for the #CRC) characters constituting the file name at this step in the process, followed by the separator ‘#’ (#0023); followed by a 4 digit CS0 Hex representation of the 16-bit CRC of the original CS0 *FileIdentifier*, followed by ‘.’ (#002E) and the *file extension* at this step in the process.

   Otherwise if there is no *file extension* the new *FileIdentifier* shall be composed of up to the first (31 – 5(for the #CRC)) characters constituting the *file name* at this step in the process. Followed by the separator ‘#’ (#0023); followed by a 4 digit CS0 Hex representation of the 16-bit CRC of the original CS0 *FileIdentifier*.

### 4.2.2.1.4 Windows 95 & Windows NT

Due to the restrictions imposed by the Windows 95 and Windows NT operating system environments, on the *FileIdentifier* associated with a file the following methodology shall be employed to handle *FileIdentifier(s)* under the above-mentioned operating system environment:

1. **FileIdentifier Lookup**: Upon request for a “lookup” of a *FileIdentifier*, a case-sensitive comparison may be performed. If the case-sensitive comparison is not done or if it fails, a case-insensitive comparison shall be performed.

2. **Validate FileIdentifier**: If the *FileIdentifier* is a valid file identifier for Windows 95 or Windows NT then do not apply the following steps.
3. **Invalid Characters:** A *FileIdentifier* that contains characters considered invalid within a file name of the supported operating system, or not displayable in the current environment shall have them translated into “_” (#005F). Multiple sequential invalid or non-displayable characters shall be translated into a single “_” (#005F) character. Reference the appendix on invalid characters for a complete list.

4. **Trailing Periods and Spaces:** All trailing “.” (#002E) and “ ” (#0020) shall be removed.

5. **FileIdentifier CRC:** Since through the above process character information from the original *FileIdentifier* is lost the chance of creating a duplicate *FileIdentifier* in the same directory increases. To greatly reduce the chance of having a duplicate *FileIdentifier* the file name shall be modified to contain a CRC of the original *FileIdentifier*.

   If there is a *file extension* then the new *FileIdentifier* shall be composed of up to the first \((255 - (\text{length of (new file extension)} + 1 \text{ for the ‘.’}) - 5 \text{ (for the CRC)})\) characters constituting the *file name* at this step in the process, followed by the separator ‘#’ (#0023); followed by a 4 digit CS0 Hex representation of the 16-bit CRC of the original CS0 *FileIdentifier*, followed by ‘.’ (#002E) and the *file extension* at this step in the process.

   Otherwise if there is no *file extension* the new *FileIdentifier* shall be composed of up to the first \((255 - 5 \text{ (for the #CRC)})\) characters constituting the *file name* at this step in the process. Followed by the separator ‘#’ (#0023); followed by a 4 digit CS0 Hex representation of the 16-bit CRC of the original CS0 *FileIdentifier*.

4.2.2.1.5 **UNIX**

Due to the restrictions imposed by UNIX operating system environments, on the *FileIdentifier* associated with a file the following methodology shall be employed to handle *FileIdentifier*(s) under the above-mentioned operating system environment:

1. **FileIdentifier Lookup:** Upon request for a “lookup” of a *FileIdentifier*, a case-sensitive comparison shall be performed.

2. **Validate FileIdentifier:** If the *FileIdentifier* is a valid UNIX file identifier for the current system environment then do not apply the following steps.

3. **Invalid Characters:** A *FileIdentifier* that contains characters considered invalid within a UNIX file name for the current system environment, or not displayable in the current environment shall have them translated into “_” (#005E). Multiple sequential invalid or non-displayable characters shall be translated into a single “_” (#005E) character. Reference the appendix on invalid characters for a complete list.
4. Long FileIdentifier – In the event that the number of characters constituting the FileIdentifier at this step in the process is greater than MAXNameLength (maximum name length for the specific UNIX operating system), the new FileIdentifier will consist of the first MAXNameLength-5 characters of the FileIdentifier at this step in the process.

5. FileIdentifier CRC Since through the above process character information from the original FileIdentifier is lost the chance of creating a duplicate FileIdentifier in the same directory increases. To greatly reduce the chance of having a duplicate FileIdentifier the file name shall be modified to contain a CRC of the original FileIdentifier.

If there is a file extension then the new FileIdentifier shall be composed of up to the first (MAXNameLength – (length of (new file extension) + 1 (for the ‘.’)) – 5 (for the #CRC)) characters constituting the file name at this step in the process, followed by the separator ‘#’ (#0023); followed by a 4 digit CS0 Hex representation of the 16-bit CRC of the original CS0 FileIdentifier, followed by ‘.’ (#002E) and the file extension at this step in the process.

Otherwise if there is no file extension the new FileIdentifier shall be composed of up to the first (MAXNameLength – 5 (for the #CRC)) characters constituting the file name at this step in the process. Followed by the separator ‘#’ (#0023); followed by a 4 digit CS0 Hex representation of of the 16-bit CRC of the original CS0 FileIdentifier.

4.2.2.1.6 OS/400
Due to the restrictions imposed by OS/400 operating system environments, on the FileIdentifier associated with a file the following methodology shall be employed to handle FileIdentifier(s) under the above mentioned operating system environment.

1. FileIdentifier Lookup: Upon request for a “lookup” of a FileIdentifier, a case-sensitive comparison may be performed. If the case-sensitive comparison is not done or if it fails, a case-insensitive comparison shall be performed.

2. Validate FileIdentifier: If the FileIdentifier is a valid file identifier for OS/400 then do not apply the following steps.

3. Invalid Characters: A FileIdentifier that contains characters considered invalid within an OS/400 file name, or not displayable in the current environment shall have them translated into “_” (#005F). Multiple sequential invalid or non-displayable characters shall be translated into a single “_” (#005F) character.

4. Trailing Spaces: All trailing “ “(#0020) shall be removed.
5. FileIdentifier CRC: Since through the above process character information from the original FileIdentifier is lost the chance of creating a duplicate FileIdentifier in the same directory increases. To greatly reduce the chance of having a duplicate FileIdentifier the filename shall be modified to contain a CRC of the original FileIdentifier.

If there is a file extension then the new FileIdentifier shall be composed of up to the first \((255 - (\text{length of (new file extension)} + 1 \text{ (for the "."))}) - 5 \text{ (for the #CRC)})\) characters constituting the file name at this step in the process, followed by the separator “#” (#0023); followed by a 4 digit CS0 Hex representation of the 16 –bit CRC of the original CS0 FileIdentifier, followed by “.” (#002E) and the file extension at this step in the process.

Otherwise if there is no file extension the new FileIdentifier shall be composed of up to the first \((255 - 5 \text{ (for the new #CRC)})\) characters constituting the file name at this step in the process. Followed by the separator “#” (#0023); followed by a 4 digit CS0 hex representation of the 16-bit CRC of the original CS0 FileIdentifier.

Note: Invalid characters for OS/400 are only the forward slash “/” (#002F) character. Non-displayable characters for OS/400 are any characters that do not translate to code page 500 (EBCDIC Multilingual).
5. Informative

5.1 Descriptor Lengths

The following table summarizes the UDF limitations on the lengths of the Descriptors described in ECMA 167.

<table>

5.2 Using Implementation Use Areas
5.2.1 Entity Identifiers
Refer to section 2.1.5 on Entity Identifiers defined earlier in this document.

5.2.2 Orphan Space
Orphan space may exist within a logical volume, but it is not recommended since some type of logical volume repair facility may reallocate it. Orphan space is defined as space that is not directly or indirectly referenced by any of the non-implementation use descriptors defined in ECMA 167.

NOTE: Any allocated extent for which the only reference resides within an implementation use field is considered orphan space.

5.3 Boot Descriptor
T.B.D.

5.4 Clarification of Unrecorded Sectors
ECMA 167 section 3/8.1.2.2 states

Any unrecorded constituent sector of a logical sector shall be interpreted as containing all #00 bytes. Within the sector containing the last byte of a logical sector, the interpretation of any bytes after that last byte is not specified by this Part.

A logical sector is unrecorded if the standard for recording allows detection that a sector has been unrecorded and all of the logical sector’s constituent sectors are unrecorded. A logical sector should either be completely recorded or unrecorded.

For the purposes of interchange, UDF must clarify the correct interpretation of this section.

This part specifies that an unrecorded sector logically contains #00 bytes. However, the converse argument that a sector containing only #00 bytes is unrecorded is not implied, and such a sector is not an “unrecorded” sector for the purposes of ECMA. Only the standard governing the recording of sectors on the media can provide the rule for determining if a sector is unrecorded. For example, a blank check condition would provide correct determination for a WORM device.
The following additional ECMA 167 sections reference the rule defined 3/8.1.2.2: 3/8.4.2, 3/8.8.2, 4/3.1, 4/8.3.1 and 4/8.10. By derivation, UDF 6.6 (strategy 4096) is also affected. Since unrecorded sectors/blocks are terminating conditions for sequences of descriptors, an implementation must be careful to know that the underlying storage media provides a notion of unrecorded sectors before assuming that not writing to a sector is detectable. Otherwise, reliance on the incorrect converse argument mentioned above may result. Explicit termination descriptors must be used when an appropriate unrecorded sector would be undetectable.

6.3 Operating System Identifiers

The following tables define the current allowable values for the OS Class and OS Identifier fields in the IdentifierSuffix of Entity Identifiers.

The OS Class field will identify under which class of operating system the specified descriptor was recorded. The valid values for this field are as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Operating System Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Undefined</td>
</tr>
<tr>
<td>1</td>
<td>DOS</td>
</tr>
<tr>
<td>2</td>
<td>OS/2</td>
</tr>
<tr>
<td>3</td>
<td>Macintosh OS</td>
</tr>
<tr>
<td>4</td>
<td>UNIX</td>
</tr>
<tr>
<td>5</td>
<td>Windows 9x</td>
</tr>
<tr>
<td>6</td>
<td>Windows NT</td>
</tr>
<tr>
<td>7</td>
<td>OS/400</td>
</tr>
<tr>
<td>8</td>
<td>BeOS</td>
</tr>
<tr>
<td>9</td>
<td>Windows CE</td>
</tr>
<tr>
<td>10-255</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

The OS Identifier field will identify under which operating system the specified descriptor was recorded. The valid values for this field are as follows:

<table>
<thead>
<tr>
<th>OS Class</th>
<th>OS Identifier</th>
<th>Operating System Identified</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Any Value</td>
<td>Undefined</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>DOS/Windows 3.x</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>OS/2</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
<td>Macintosh OS</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>UNIX - Generic</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>UNIX - IBM AIX</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>UNIX - SUN OS / Solaris</td>
</tr>
<tr>
<td>4</td>
<td>3</td>
<td>UNIX - HP/UX</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>UNIX - Silicon Graphics Irix</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
<td>UNIX - Linux</td>
</tr>
<tr>
<td>4</td>
<td>6</td>
<td>UNIX - MKLinux</td>
</tr>
<tr>
<td>4</td>
<td>7</td>
<td>UNIX - FreeBSD</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
<td>Windows 9x – generic (includes Windows 98)</td>
</tr>
<tr>
<td>6</td>
<td>0</td>
<td>Windows NT – generic (includes Windows 2000)</td>
</tr>
<tr>
<td>7</td>
<td>0</td>
<td>OS/400</td>
</tr>
<tr>
<td>8</td>
<td>0</td>
<td>BeOS - generic</td>
</tr>
<tr>
<td>9</td>
<td>0</td>
<td>Windows CE - generic</td>
</tr>
</tbody>
</table>

For the most up to date list of values for OS Class and OS Identifier please contact OSTA and request a copy of the *UDF Entity Identifier Directory*. This directory will also contain Implementation Identifiers of ISVs who have provided the necessary information to OSTA.
6.4 OSTA Compressed Unicode Algorithm

#include <stddef.h>

/* The following two typedef’s are to remove compiler dependancies. 
* byte needs to be unsigned 8-bit, and unicode_t needs to be 
* unsigned 16-bit. 
*/
typedef unsigned short unicode_t;
typedef unsigned char byte;

/* Takes an OSTA CS0 compressed unicode name, and converts 
* it to Unicode. 
* The Unicode output will be in the byte order 
* that the local compiler uses for 16-bit values. 
* NOTE: This routine only performs error checking on the compID. 
* It is up to the user to ensure that the unicode buffer is large 
* enough, and that the compressed unicode name is correct. 
* 
* RETURN VALUE 
* 
* The number of unicode characters which were uncompressed. 
* A -1 is returned if the compression ID is invalid. 
*/
int UncompressUnicode(
    int numberOfBytes,  /* (Input) number of bytes read from media. */
    byte *UDFCompressed, /* (Input) bytes read from media. */
    unicode_t *unicode)  /* (Output) uncompressed unicode characters. */
{
    unsigned int compID;
    int returnValue, unicodeIndex, byteIndex;

    /* Use UDFCompressed to store current byte being read. */
    compID = UDFCompressed[0];

    /* First check for valid compID. */
    if (compID != 8 && compID != 16)
    {
        returnValue = -1;
    }
    else
    {
        unicodeIndex = 0;
        byteIndex = 1;

        /* Loop through all the bytes. */
        while (byteIndex < numberOfBytes)
        {
            if (compID == 16)
/*Move the first byte to the high bits of the unicode char.*/
unicode[unicodeIndex] = UDFCompressed[byteIndex++] << 8;

else
{
    unicode[unicodeIndex] = 0;
}

if (byteIndex < numberOfBytes)
{
    /*Then the next byte to the low bits.*/
    unicode[unicodeIndex] |= UDFCompressed[byteIndex++];
}

unicodeIndex++;

returnValue = unicodeIndex;

return(returnValue);

}
unicodeIndex = 0;
while (unicodeIndex < numberOfChars)
{
    if (compID == 16)
    {
        /* First, place the high bits of the char
         * into the byte stream.
         */
        UDFCompressed[byteIndex++] =
            (unicode[unicodeIndex] & 0xFF00) >> 8;
    }
    /* Then place the low bits into the stream. */
    UDFCompressed[byteIndex++] = unicode[unicodeIndex] & 0x00FF;
    unicodeIndex++;
}
return(byteIndex);
6.5 CRC Calculation

The following C program may be used to calculate the CRC-CCITT checksum used in the TAG descriptors of ECMA 167.

/*
  * CRC 010041
*/
static unsigned short crc_table[256] = {
  0x0000, 0x1021, 0x2042, 0x3063, 0x4084, 0x50A5, 0x60C6, 0x70E7,
  0x8108, 0x9129, 0xA14A, 0xB16B, 0xC18C, 0xD1AD, 0xE1CE, 0xF1EF,
  0x02B0, 0x1291, 0x22F2, 0x32D3, 0x4234, 0x5215, 0x6276, 0x7257,
  0x83B8, 0x9399, 0xA3FA, 0xB3DB, 0xC37C, 0xD35D, 0xE33E, 0xF31F,
  0x04D0, 0x14B1, 0x2432, 0x3413, 0x4474, 0x54F5, 0x65D6, 0x75F7,

### 6.6 Algorithm for Strategy Type 4096

This section describes a strategy for constructing an ICB hierarchy. For strategy type 4096 the root ICB hierarchy shall contain 1 direct entry and 1 indirect entry. To indicate that there is 1 direct entry a 1 shall be recorded as a Uint16 in the `StrategyParameter` field of the ICB Tag field. A value of 2 shall be recorded in the `MaximumNumberOfEntries` field of the ICB Tag field.

The indirect entry shall specify the address of another ICB which shall also contain 1 direct entry and 1 indirect entry, where the indirect entry specifies the address of another ICB of the same type. See the figure below:

![Diagram](image.png)

**NOTE:** This strategy builds an ICB hierarchy that is a simple linked list of direct entries.
6.7 Identifier Translation Algorithms

The following sample source code examples implement the file identifier translation algorithms described in this document.

The following basic algorithms may also be used to handle OS specific translations of the VolumeIdentifier, VolumeSetIdentifier, LogicalVolumeID and FileSetID.

6.7.1 DOS Algorithm

```c
/* OSTA UDF compliant file name translation routine for DOS and Windows short namespaces. */
/* Define constants for namespace translation */
#define DOS_NAME_LEN 8
#define DOS_EXT_LEN 3
#define DOS_LABEL_LEN 11
#define DOS_CRC_LEN 4
#define DOS_CRC_MODULUS 41

/* Define standard types used in example code. */
typedef BOOLEAN int;
typedef short INT16;
typedef unsigned short UINT16;
typedef UINT16 UNICODE_CHAR;
#define FALSE 0
#define TRUE 1

static char crcChar[] = 
"0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZ#_~-@";

/* FUNCTION PROTOTYPES */
UNICODE_CHAR UnicodeToUpper(UNICODE_CHAR value);
BOOLEAN IsFileNameCharLegal(UNICODE_CHAR value);
BOOLEAN IsVolumeLabelCharLegal(UNICODE_CHAR value);
INT16 NativeCharLength(UNICODE_CHAR value);

    return(checksum);
}
6.9 Requirements for DVD-ROM
This appendix defines the requirements and restrictions for UDF formatted DVD-ROM discs.

- DVD-ROM discs shall be mastered with the UDF file system
- DVD-ROM discs shall consist of a single volume and a single partition.

**NOTE:** The disc may also include the ISO 9660 file system. If the disc contains both UDF and ISO 9660 file systems it shall be known as a *UDF Bridge* disc. This *UDF Bridge* disc will allow playing DVD-ROM media in computers, which may only support ISO 9660. As UDF computer implementations are provided, the need for ISO 9660 will disappear, and future discs should contain only UDF.

6.9.1 Constraints imposed on UDF by DVD-Video
This section describes the restrictions and requirements for UDF formatted DVD-Video discs for dedicated DVD content players. DVD-Video is one specific application of DVD-ROM using the UDF format for the home consumer market. Due to limited computing resources within a DVD player, restrictions and requirements were created so that a DVD player would not have to support every feature of the UDF specification.

All DVD-Video discs shall be mastered to contain all required data as specified by ECMA 167 (2nd edition) and UDF 1.02. This will ease playing of DVD-Video in computer systems. Examples of such data include the time, date, permission bits, and a free space map (indicating no free space). While DVD player implementations may ignore these fields, a UDF computer system implementation will not. Both entertainment-based and computer-based content can reside on the same disc.

**NOTE:** DVD-Video discs mastered according to UDF 2.0x may not be compatible with DVD-Video players. DVD-Video players expect media in UDF 1.02 format.

In an attempt to reduce code size and improve performance, all division described is integer arithmetic; all denominators shall be $2^n$, such that all divisions may be carried out via logical shift operations.

- A DVD player shall only support UDF and not ISO 9660.
- Originating systems shall constrain individual files to be less than or equal to $2^{30} - \text{Logical Block Size}$ bytes in length.
• The data of each file shall be recorded as a single extent. Each File Entry shall be recorded using the ICB Strategy Type 4.

• File and directory names shall be compressed as 8 bits per character using OSTA Compressed Unicode format.

• A DVD player shall not be required to follow symbolic links to any files.

• The DVD-Video files shall be stored in a subdirectory named "VIDEO_TS" directly under the root directory. Directory names are standardized in the DVD Specifications for Read-Only Disc document.

NOTE: The DVD Specifications for Read-Only Disc is a document, developed by the DVD Consortium, that describes the names of all DVD-Video files and a DVD-Video directory, which will be stored on the media, and additionally, describes the contents of the DVD-Video files.

• The file named "VIDEO_TS.IFO" in the VIDEO_TS subdirectory shall be read first.

All the above constraints apply only to the directory and files that the DVD player needs to access. There may be other files and directories on the media which are not intended for the DVD player and do not meet the above listed constraints. These other files and directories are ignored by the DVD player. This is what enables the ability to have both entertainment-based and computer-based content on the same disc.

6.9.2 How to read a UDF DVD-Video disc

This section describes the basic procedures that a DVD player would go through to read a UDF formatted DVD-Video disc.

6.9.2.1 Step 1. Volume Recognition Sequence

Find an ECMA 167 Descriptor in a volume recognition area, which shall start at logical sector 16.

6.9.2.2 Step 2. Anchor Volume Descriptor Pointer

The Anchor Volume Descriptor Pointer, which is located at an anchor point, must be found. Duplicate anchor points shall be recorded at logical sector 256 and logical sector n, where n is the highest numbered logical sector on the disc.

A DVD player only needs to look at logical sector 256; the copy at logical sector n is redundant and only needed for defect tolerance. The Anchor Volume Descriptor Pointer contains three things of interest:

1. Static structures that may be used to identify and verify integrity of the disc.
2. Location of the Main Volume Descriptor Sequence (absolute logical sector number)
3. Length of the Main Volume Descriptor Sequence (bytes)
The data located in bytes 0-3 and 5 of the Anchor Volume Descriptor Pointer may be used for format verification if desired. Verifying the checksum in byte 4 and CRC in bytes 8-11 are good additional verifications to perform. MVDS_Location and MVDS_Length are read from this structure.

6.9.2.3 Step 3. Volume Descriptor Sequence
Read logical sectors:

MVDS_Location through MVDS_Location + (MVDS_Length - 1) / SectorSize

The logical sector size shall be 2048 bytes for DVD media. If this sequence cannot be read, a Reserve Volume Descriptor Sequence should be read.

The Partition Descriptor shall be a descriptor with a tag identifier of 5. The partition number and partition location shall be recorded in logical sector number.

Partition_Location and Partition_Length are obtained from this structure.

The Logical Volume Descriptor shall be a descriptor with a tag identifier of 6. The location and length of the File Set Descriptor shall be recorded in the Logical Volume Descriptor.

FSD_Location, and FSD_Length are returned from this structure.

6.9.2.4 Step 4. File Set Descriptor
The File Set Descriptor is located at logical sector numbers:

Partition_Location + FSD_Location through
Partition_Location + FSD_Location + (FSD_Length - 1) / BlockSize

RootDir_Location and RootDir_Length shall be read from the File Set Descriptor in logical block number.

6.9.2.5 Step 5. Root Directory File Entry
RootDir_Location and RootDir_Length define the location of a File Entry. The File Entry describes the data space and permissions of the root directory.

The location and length of the Root Directory is returned.

6.9.2.6 Step 6. Root Directory
Parse the data in the root directory extent to find the VIDEO_TS subdirectory.
Find the VIDEO_TS File Identifier Descriptor. The name shall be in 8 bit compressed UDF format. Verify that VIDEO_TS is a directory.

Read the File Identifier Descriptor and find the location and length of a File Entry describing the VIDEO_TS directory.

6.9.2.7 Step 7. File Entry of VIDEO_TS
The File Entry found in the step above describes the data space and permissions of the VIDEO_TS directory.

The location and length of the VIDEO_TS directory is returned.

6.9.2.8 Step 8. VIDEO_TS directory
The extent found in the step above contains sets of File Identifier Descriptors. In this pass, verify that the entry points to a file and is named VIDEO_TS.IFO.

6.9.2.9 Step 9. File Entry of VIDEO_TS.IFO
The File Entry found in the step above describes the data space and permissions of the VIDEO_TS.IFO file.

The location and length of the VIDEO_TS.IFO file is returned.

Further files can be found in the same manner as the VIDEO_TS.IFO file when needed.
6.10 Recommendations for CD Media

CD Media (CD-R and CD-RW) requires special consideration due to its nature. CD was originally designed for read-only applications, which affects the way in which it is written. The following guidelines are established to ensure interchange.

Each file and directory shall be described by a single direct ICB. The ICB should be written after the file data to allow for data underruns during writing, which will cause logical gaps in the file data. The ICB can be written afterward which will correctly identify all extents of the file data. The ICB shall be written in the data track, the file system track (if it exists), or both.

6.10.1 Use of UDF on CD-R media

ECMA 167 requires an Anchor Volume Descriptor Pointer (AVDP) at sector 256 and either \( N \) or \( (N - 256) \), where \( N \) is the last recorded Physical Address on the media. UDF requires that the AVDP be recorded at both sector 256 and sector \( (N - 256) \) when each session is closed (2.2.3). The file system may be in an intermediate state before closing and still be interchangeable, but not strictly in compliance with ECMA 167. In the intermediate state, only one AVDP exists. It should exist at sector 256, but if this is not possible due to a track reservation, it shall exist at sector 512.

Implementations should place file system control structures into virtual space and file data into real space. Reader implementations may cache the entire VAT; the size of the VAT should be considered by any UDF originating software. Computer based implementations are expected to handle VAT sizes of at least 64K bytes; dedicated player implementations may handle only smaller sizes.

The VAT may be located by using READ TRACK INFORMATION (for unfinished media) or READ TOC or READ CD RECORDED CAPACITY for finished media. See X3T10-1048D (SCSI-3 Multi Media Commands).

6.10.1.1 Requirements

- Writing shall use Mode 1 or Mode 2 Form 1 sectors. On one disc, either Mode 1 or Mode 2 Form 1 shall be used; a mixture of Mode 1 and Mode 2 Form 1 sectors on one disc is not allowed.
  
  **NOTE:** According to the Multisession CD Specification, all data sessions on a disc must be of the same type (Mode 1, or Mode 2 Form 1).

- If Mode 2 Form 1 is used, then the subheader bytes of all sectors used by the user data files and by the UDF structures shall have the following value:

  - File number = 0
  - Channel number = 0
  - Submode = 08h
  - Coding information = 0
• An intermediate state is allowed on CD-R media in which only one AVDP is recorded; this single AVDP shall be at sector 256 or sector 512 and according to the multi-session rules below.

• Sequential file system writing shall be performed with variable packet writing. This allows maximum space efficiency for large and small updates. Variable packet writing is more compatible with CD-ROM drives, as current models do not support method 2 addressing required by fixed packets.

• The Logical Volume Integrity descriptor shall be recorded and the volume marked as open. Logical volume integrity can be verified by finding the VAT ICB at the last recorded Physical Address. If the VAT ICB is present, the volume is clean; otherwise it is dirty.

• The Partition Header descriptor, if recorded, shall specify no Unallocated Space Table, no Unallocated Space Bitmap, no Partition Integrity Table, no Freed Space Table, and no Freed Space Bitmap. The drive is capable of reporting free space directly, eliminating the need for a separate descriptor.

• Each surface shall contain 0 or 1 read only partitions, 0 or 1 write once partitions, and 0 or 1 virtual partitions. CD media should contain 1 write once partition and 1 virtual partition.

6.10.1.2 UDF “Bridge” formats
ISO 9660 requires a Primary Volume Descriptor (PVD) at sector 16. If an ISO 9660 file system is desired, it may contain references to the same files as those referenced by ECMA 167 structures, or reference a different set of files, or a combination of the two.

It is assumed that early implementations will record some ISO 9660 structures but that as implementations of UDF become available, the need for ISO 9660 structures will decrease.

If an ISO 9660 bridge disc contains Mode 2 Form 1 sectors, then the CD-ROM XA extensions for ISO 9660 must be used.

6.10.1.3 End of session data
A session is closed to enable reading by CD-ROM drives. The last complete session on the disc shall conform completely to ECMA 167 and have two AVDPs recorded. This shall be accomplished by writing data according to End of session data table below. Although not shown in the following example, the data may be written in multiple packets.
The implementation specific data may contain repeated copies of the VAT and VAT ICB. Compatibility with drives that do not accurately report the location of the last sector will be enhanced. Implementations shall ensure that enough space is available to record the end of session data. Recording the end of session data brings a volume into compliance with ECMA 167.

### 6.10.2 Use of UDF on CD-RW media

CD-RW media is randomly readable and block writable. This means that while any individual sector may be read, writing must occur in blocks containing multiple sectors. CD-RW systems do not provide for sparing of bad areas. Writing rules and sparing mechanisms have been defined.

#### 6.10.2.1 Requirements

- Writing which conforms to this section of the standard shall be performed using fixed length packets.

- Writing shall be performed using Mode 1 or Mode 2, Form 1 sectors. On one disc, either Mode 1 or Mode 2 Form 1 shall be used.

  **NOTE:** According to the Multisession CD Specification, all data sessions on a disc must be of the same type (Mode 1, or Mode 2 Form 1).

- If Mode 2 Form 1 is used, then the subheader bytes of all sectors used by the user data files and by the UDF structures shall have the following value:

  File number = 0
  Channel number = 0
  Submode = 08h
  Coding information = 0

---

**End of session data**

</tbody>
</table>
• The host shall perform read/modify/write to enable the apparent writing of single 2K sectors.

• The packet length shall be set when the disc is formatted. The packet length shall be 32 sectors (64 KB).

• The host shall maintain a list of defects on the disc using a Non-Allocatable Space Stream (see 3.3.7.2).

• Sparing shall be managed by the host via the sparable partition and a sparing table.

• Discs shall be formatted prior to use.

6.10.2.2 Formatting
Formatting shall consist of writing a lead-in, user data area, and lead-out. These areas may be written in any order. A verification pass may follow this physical format. Defects found during the verification pass shall be enumerated in the Non-Allocatable Space Stream (see 3.3.7.2). Finally, file system root structures shall be recorded. These mandatory file system and root structures include the Volume Recognition Sequence, Anchor Volume Descriptor Pointers, a Volume Descriptor Sequence, a File Set Descriptor and a Root Directory.
The Anchor Volume Descriptor Pointers shall be recorded at sectors 256 and N - 256, where N is the Physical Address of the last addressable sector.
Allocation for sparing shall occur during the format process. The sparing allocation may be zero in length.
The free space descriptors shall be recorded and shall reflect space allocated to defective areas and sector sparing areas.
The format may include all available space on the medium. However, if requested by the user, a subset may be formatted to save formatting time. That smaller format may be later “grown” to the full available space.
6.10.2.3 Growing the Format
If the medium is partially formatted, it may be later grown to a larger size. This operation consists of:

• Optionally erase the lead-in of the last session.

• Optionally erase the lead-out of the last session.

• Write packets beginning immediately after the last recorded packet.

• Update the sparing table to reflect any new spare areas

• Adjust the partition map as appropriate

• Update the free space map to show new available area

• Move the last AVDP to the new N - 256

• Write the lead-in (which reflects the new track size)

• Write the lead-out

6.10.2.4 Host Based Defect Management
The host shall perform defect management operations. The CD format was defined without any defect management; to be compatible with existing technology and components, the host must manage defects. There are two levels of defect management: Marking bad sectors at format time and on-line sparing. The host shall keep the tables on the media current.

6.10.2.5 Read Modify Write Operation
CD-RW media requires large writable units, as each unit incurs a 14KB overhead. The file system requires a 2KB writable unit. The difference in write sizes is handled by a read-modify-write operation by the host. An entire packet is read, the appropriate portions are modified, and the entire packet written to the CD.

Note that packets may not be aligned to 32 sector boundaries.

6.10.2.6 Levels of Compliance
6.10.2.6.1 Level 1
The disc shall be formatted with exactly one lead-in, program area, and lead-out. The program area shall contain exactly one track.

6.10.2.6.2 Level 2
The last session shall contain the UDF file system. All prior sessions shall be contained in one read-only partition.
6.10.2.6.3 Level 3
No restrictions shall apply.

6.10.3 Multisession and Mixed Mode
The Volume Recognition Sequence and Anchor Volume Descriptor Pointer locations are specified by ECMA 167 to be at a location relative to the beginning of the disc. The beginning of a disc shall be determined from a base address \( S \) for the purposes of finding the VRS and AVDP.

\( S \) is the Physical Address of the first data sector in the first recorded data track in the last existent session of the volume. \( S \) is the same value currently used in multisession ISO 9660 recording. The first track in the session shall be a data track.

\( N \) is the physical sector number of the last recorded data sector on a disc.
If random write mode is used, the media may be formatted with zero or one audio sessions followed by exactly one writable data session containing one track. Other session configurations are possible but not described here. There shall be no more than one writable partition or session at one time, and this session shall be the last session on the disc.

6.10.3.1 Volume Recognition Sequence
The following descriptions are added to UDF (see also ECMA 167 Part 2) in order to handle a multisession disc.

- The volume recognition area of the UDF Bridge format shall be the part of the volume space starting at sector \( S + 16 \).
- The volume recognition space shall end in the track in which it begins. As a result of this definition, the volume recognition area always exists in the last session of a disc.
- When recorded in Random Access mode, a duplicate Volume Recognition Sequence should be recorded beginning at sector \( N - 16 \).

6.10.3.2 Anchor Volume Descriptor Pointer
Anchor Volume Descriptor Pointers (AVDP) shall be recorded at the following logical sector numbers: \( S + 256 \) and \( N - 256 \). The AVDP at sector \( N - 256 \) shall be recorded before closing a session; it may not be recorded while a session is open.

6.10.3.3 UDF Bridge format
The UDF Bridge format allows UDF to be added to a disc that may contain another file system. A UDF multisession Bridge disc shall contain a UDF file system in its last session. The last session shall follow the rules described in “Multisession and Mixed Mode” section above. The disc may contain sessions that are based on ISO 9660, audio, vendor unique, or a combination of file systems. The UDF Bridge format allows CD enhanced discs to be created.

A new Main and Reserve Volume Descriptor Sequence may exist in each added session, and may be different than earlier VDSs.
If the last session on a CD does not contain a valid UDF file system, the disc is not a UDF disc. Only the UDF structures in the last session, and any UDF structures and data referenced through them, are valid.

The UDF session may contain pointers to data or metadata in other sessions, pointers to data or metadata only within the UDF session, or a combination of both. Some examples of UDF Bridge discs are shown below.
### 6.11 Real-Time Files

A Real-Time file is a file that requires a minimum data-transfer rate when writing or reading, for example, audio and video data. For these files special read and write commands are needed. For example for CD and DVD devices these special commands can be found in the Mount Fuji 4 specification.

A Real-Time file shall be identified by file type 249 in the File Type field of the file's ICB Tag.
7. UDF 2.01 ERRATA

7.1 Requirements for DVD-RAM/RW/R interchangeability

Description:
Requirements for DVD-RAM, DVD-RW, and DVD-R discs to be used with consumer appliances (e.g. dedicated DVD content recorder/player) are specified as a new appendix for UDF 2.00 and 2.01 to improve data interchangeability among these appliances and computer systems.

Change:
Add new appendix 6.12 as:

6.12 Requirements for DVD interchangeability
This appendix defines the requirements and restrictions on volume and file structures for writable DVD media, including but not limited to DVD-RAM discs (6.12.1), DVD-RW discs (6.12.2) and DVD-R discs (6.12.3), to support the interchange of information between users of both computer systems and consumer appliances. These requirements do not apply to the discs that are used in a computer system environment only and have no interchangeability with consumer appliances. The common requirements for these DVD discs are summarized as follows:
  1. The volume and file structure shall comply with UDF 2.00.
  2. The Minimum UDF Read Revision and Minimum UDF Write Revision shall be 2.00.
  3. The length of logical sector and logical block shall be 2048 bytes.
  4. A Main Volume Descriptor Sequence and a Reserve Volume Descriptor Sequence shall be recorded.

6.12.1 Requirements for DVD-RAM
The requirements for DVD-RAM discs are based on UDF 2.00. The volume and file structure is simplified as for overwritable discs using non-sequential recording.

For Volume Structure:
  1. A partition on a DVD-RAM disc shall be an overwritable partition specified as access type 4.
  2. Virtual Partition Map and Virtual Allocation Table shall not be recorded.
  3. Sparable Partition Map and Sparing Table shall not be recorded.
For File Structure:
4. Unallocated Space Table or Unallocated Space Bitmap shall be used to indicate a
space set. Freed Space Table and Freed Space Bitmap shall not be recorded.
5. Non-Allocatable Space Stream shall not be recorded.

6.12.2 Requirements for DVD-RW
The requirements for DVD-RW discs under Restricted Overwrite mode are based on
UDF 2.00. The volume and file structure is simplified as for rewritable discs using non-
sequential recording.

For Volume Structure:
1. A disc shall consist of a single volume with a single sparing partition per side.
2. A Sparable Partition Map and Sparing Table shall be recorded.
3. Length of a packet shall be 16 sectors (32 KB) and the first sector number of a
packet shall be an integral multiple of 16.
4. Virtual Partition Map and Virtual Allocation Table shall not be recorded.

For File Structure:
5. Unallocated Space Bitmap shall be used to indicate a space set. Unallocated
Space Table, Freed Space Table and Freed Space Bitmap shall not be recorded.
6. Non-Allocatable Space Stream shall be recorded.
7. ICB Strategy type 4 shall be used.
8. Short Allocation Descriptors or the embedded data shall be recorded in the
Allocation Descriptors field of the File Entry or Extended File Entry. Long
Allocation Descriptors shall not be recorded in this field.

6.12.3 Requirements for DVD-R
The requirements for DVD-R discs under Disc at once recording mode and under
Incremental recording mode are based on UDF 2.00. The volume and file structure is
simplified as for write once discs using sequential recording.

For Volume Structure:
1. Length of a packet shall be an integral multiple of 16 sectors (32 KB) and the
first sector number of a packet shall be an integral multiple of 16.
2. Sparable Partition Map and Sparing Table shall not be recorded.
3. Under Incremental recording mode, only one Open Integrity Descriptor shall be
recorded in the Logical Volume Integrity Sequence.
4. Under Incremental recording mode, Virtual Partition Map shall be recorded.

For File Structure:
5. Unallocated Space Table, Unallocated Space Bitmap, Freed Space Table and
Freed Space Bitmap shall not be recorded.
6. Only one File Set Descriptor shall be recorded.
7. Non-Allocatable Space Stream shall not be recorded.
8. Under Incremental recording mode, Virtual Allocation Table and VAT ICB shall be recorded.
9. Under Incremental recording mode, ICB Strategy type 4 shall be used.
10. Under Incremental recording mode, the VAT entries in VAT shall be assigned as follows:
    - The virtual address 0 shall be used for File Set Descriptor.
    - The virtual address 1 shall be used for the ICB of the root directory.
    - The virtual addresses in the range of 2 to 255 shall be assigned for the File Entry of DVD_RTAV directory and File Entries of files under the DVD_RTAV directory.

6.12.4 Requirements for Real-Time file recording on DVD discs

DVD Video Recording specification defines the DVD specific sub-directory "DVD_RTAV" and all DVD specific files under the DVD_RTAV directory. DVD specific files consist of Real-Time files with the file type 249 and the related information files.

For Volume Structure:
1. For DVD-RAM/RW discs, a disc shall consist of a single volume with a single partition per side. For DVD-R discs, a disc shall consist of a single volume with a write once partition and a virtual partition per side.
2. For DVD-RW discs, First Sparing Table and Second Sparing Table shall be recorded.

For File Structure:
3. For DVD-RAM/RW discs, only Unallocated Space Bitmap shall be used.
4. For DVD-RW discs, the extent of Unallocated Space Bitmap should have the length of Space Bitmap Descriptor for the available Data Recordable area.
5. Consumer Content Recorders record all their data in a special subdirectory, DVD_RTAV, located in the root directory. The DVD_RTAV directory and its contents have special file system restrictions which are defined in DVD Specifications published from DVD Format/Logo Licensing Corporation. An implementation or application should not create or modify files in this directory unless it meets the restrictions defined by DVD Specifications specified above.
